27 Sir,

28           The CLSI recently published new interpretive criteria for the anti-pseudomonal  
29 penicillins and carbapenems for susceptibility testing of *Pseudomonas aeruginosa* [1]. The  
30 susceptible breakpoints for piperacillin and piperacillin-tazobactam were lowered from  $\geq 18$   
31 mm (piperacillin component, MIC  $\leq 64$   $\mu\text{g/ml}$ ) to  $\geq 21$  mm (MIC  $\leq 16$   $\mu\text{g/ml}$ ); that for  
32 ticarcillin-clavulanate and imipenem were lowered from  $\geq 15$  mm (ticarcillin component,  $\leq 64$   
33  $\mu\text{g/ml}$ ) to  $\geq 24$  mm ( $\leq 16$   $\mu\text{g/ml}$ ) and from  $\geq 16$  mm ( $\leq 4$   $\mu\text{g/ml}$ ) to  $\geq 19$  mm ( $\leq 2$   $\mu\text{g/ml}$ ),  
34 respectively [1,2]. Here, the computerized database from January 2009 to December 2011 in  
35 a clinical microbiology laboratory for *P. aeruginosa* was used to assess how implementation  
36 of the new interpretive criteria would have affected the susceptibility categorization. In the  
37 laboratory, the CLSI's disk diffusion method was used routinely for susceptibility testing of  
38 bacteria [3].

39           The results for 11540 *P. aeruginosa* isolates were analysed. Inhibition zone  
40 distributions showed that the new susceptibility breakpoints for ticarcillin-clavulanate were  
41 close to and larger than the modal value for the bacterial collection. On the other hand, the  
42 new susceptibility breakpoints for piperacillin, piperacillin-tazobactam and imipenem  
43 remained much smaller than the modal inhibition zone values. The mean ( $\pm$  standard  
44 deviation) and mode inhibition zone diameters were as follows: piperacillin, 25.9 ( $\pm 5.6$ ) and  
45 28 mm; piperacillin-tazobactam, 26.4 ( $\pm 6.6$ ) and 30 mm; ticarcillin-clavulanate, 20.8 ( $\pm 5.4$ )  
46 and 22 mm; and imipenem, 25.0 ( $\pm 5.5$ ) and 25 mm. Therefore, implementation of the new  
47 interpretive criteria (Table 1) would drastically reduce the susceptibility rate for ticarcillin-  
48 clavulanate (-49.4%). The changes in the susceptibility rates for the other three agents were  
49 modest: piperacillin (-3.5%), piperacillin-tazobactam (-2.8%) and imipenem (-1.8%). To  
50 assess the effect of the new interpretive criteria on isolates from different sources, we further  
51 analysed the results according four specimen groups (blood, urine, respiratory and other

52 specimens). At the old interpretive criteria, 83.2-84.1% of the isolates were susceptible to  
53 ticarcillin-clavulanate. When the results were interpreted by the new interpretive criteria, the  
54 ticarcillin-clavulanate susceptibility rates declined to 26.5-38.0%. The reduction in ticarcillin-  
55 clavulanate susceptibility rate was most pronounced for isolates from blood specimens (-  
56 56.6%), followed by urine (-55.9%), other specimens (-51.2%) and urine (-45.2%).

57 We submit that the new CLSI breakpoints for ticarcillin-clavulanate are debatable for  
58 several reasons. Firstly, for ticarcillin-clavulanate, the same disc content and virtually the  
59 same methodology was recommended by the CLSI and European Committee on  
60 Antimicrobial Susceptibility Testing (EUCAST) for testing *P. aeruginosa* [1,4]. According to  
61 the EUCAST, the inhibition zone diameter deems to be equivalent to the interpretive  
62 breakpoint  $\leq 16$   $\mu\text{g/ml}$  (ticarcillin component) is  $\geq 17$  mm. At the breakpoint of  $\geq 17$  mm,  
63 78.3% of the *P. aeruginosa* in this study would be classified as ticarcillin-clavulanate  
64 susceptible. Since the disc contents recommended for testing piperacillin and piperacillin-  
65 tazobactam by the CLSI and EUCAST are different, our inhibition zone distributions could  
66 not be interpreted by the EUCAST breakpoints. Secondly, it has been argued that  
67 susceptibility breakpoints should not be set to cut into the wild type inhibition zone (or MIC)  
68 distribution. Otherwise, large number of isolates would be interpreted as resistant and many  
69 isolates would shift between different interpretation categories when tested by different  
70 laboratories or upon retesting by the same laboratory. In our locality, ticarcillin-clavulanate  
71 has been widely used for treatment of various types of *P. aeruginosa* infections and clinical  
72 failures are uncommon [5]. Implementation of the new CLSI interpretive criteria would mean  
73 that very few *P. aeruginosa* isolates would then remain ticarcillin-clavulanate susceptible and  
74 clinicians would be led to prescribe other more expensive anti-pseudomonal antimicrobial  
75 agents.

87 **Table 1.** Comparison of the susceptibility rates for 11540 *P. aeruginosa* to selected antimicrobial agents using the M100-S21 and M100-S22

88 CLSI interpretive criteria

Organism and agent	% Susceptible		% Intermediate		% Resistant		Difference in % susceptible <sup>b</sup>
	CLSI-2011 <sup>a</sup>	CLSI-2012 <sup>a</sup>	CLSI-2011	CLSI-2012	CLSI-2011	CLSI-2012	
Piperacillin	92.7	89.2	-	5.7	7.3	5.1	-3.5
Piperacillin-tazobactam	93.9	91.1	-	4.4	6.1	4.4	-2.8
Ticarcillin-clavulanate	83.5	34.1	-	19.8	16.5	46.1	-49.4
Imipenem	91.3	89.5	1.1	8.7	7.6	1.7	-1.8

89 <sup>a</sup>According to the interpretive criteria published by the CLSI in January 2011 (M100-S21) [2] and January 2012 (M11-S22) for *P. aeruginosa*.

90 The 2011/2012 **CLSI breakpoints**, i.e. inhibition zone diameters (equivalent MIC), were as follows: piperacillin (with or without tazobactam),  
 91 susceptible  $\geq 18$  mm ( $\leq 64$   $\mu\text{g/ml}$ )/ **$\geq 21$  mm ( $\leq 16$   $\mu\text{g/ml}$ )**; intermediate, none/**15-20 mm (32-64  $\mu\text{g/ml}$ )**; and resistant,  $\leq 17$  mm ( $\geq 128$   $\mu\text{g/ml}$ )/ **$\leq 14$**   
 92 **mm ( $\geq 128$   $\mu\text{g/ml}$ )**; ticarcillin (with or without clavulanate), susceptible,  $\geq 15$  mm ( $\leq 64$   $\mu\text{g/ml}$ )/ **$\geq 24$  mm ( $\leq 16$   $\mu\text{g/ml}$ )**; intermediate, none/**16-23**  
 93 **mm (32-64  $\mu\text{g/ml}$ )**; and resistant,  $\leq 14$  mm ( $\geq 128$   $\mu\text{g/ml}$ )/ **$\leq 15$  mm ( $\geq 128$   $\mu\text{g/ml}$ )**; and imipenem, susceptible,  $\geq 16$  mm (4  $\mu\text{g/ml}$ )/ **$\geq 19$  mm ( $\leq$**   
 94  **$\mu\text{g/ml}$ )**; intermediate, 14-15 mm (8  $\mu\text{g/ml}$ )/**16-18 mm (4  $\mu\text{g/ml}$ )**; resistant,  $\leq 13$  mm ( $\geq 16$   $\mu\text{g/ml}$ )/ **$\leq 15$  mm ( $\geq 8$   $\mu\text{g/ml}$ )**.

95 <sup>b</sup>*P* value  $< 0.001$  for all comparisons (CLSI 2011 versus 2012).
