1 Abstract

2	A new rapid diagnostic test for detection of influenza A virus was evaluated with
3	four sets of experiments: first, a comparison with a commercial diagnostic kit against
4	a panel of virus strains was conducted; second, the kit was tested against a collection
5	of 40 strains of influenza A virus isolated from five different host species and 26
6	strains of other respiratory viruses used as controls; third, the kit was tested against
7	specimens collected in the field obtained from human and chicken; and fourth, the kit
8	was tested against the novel pandemic influenza A / H1N1 2009 clinical specimens
9	obtained from admitted to hospital patients. The test kit displayed a sensitivity of 88%
10	for both human specimens and avian specimens. The corresponding specificity was
11	99.3% for human specimens and 96.5% for avian specimens. This test kit may be
12	useful for rapid diagnosis of influenza A virus.

19	

Rapid tests for influenza are useful for the assessment of influenza-like illness in 1 the clinic. Additionally, such tests can serve as a tool for disease surveillance 2 (Pachucki, 2005). Indeed, the current epidemic of swine-origin influenza A virus 3 H1N1 (S-OIV H1N1) (Dawood et al., 2009) now designated as pandemic influenza A 4 5 / H1N1 2009 (WHO, 2009) has highlighted the need of rapid influenza diagnostic tests to facilitate early treatment of infected individuals. 6 Current rapid tests for influenza A virus are usually produced with the 7 monoclonal antibody against nucleoprotein (NP) of 498 amino acids length encoded 8 9 by influenza A virus RNA segment 5 (Yang et al., 2008). The antigenic specificity of NP is related to host species and divided into at least five distinct host-specific groups, 10 namely, human, avian, swine, equine, and gull (Gorman et al., 1990). However, 11 12 influenza A / H1N1 2009 is different from the common human influenza A virus because it contains genes from avian, human, and swine influenza viruses (Dawood et 13 al., 2009). Hence recent studies evaluating commercial rapid antigen tests with the 14 15 pandemic H1N1 viral antigen in clinical specimens showed that the sensitivity ranged from 10% to 69%, and declined substantially with lower viral titers (CDC., 2009; 16 17 Chan et al., 2009; Faix et al., 2009; Ginocchio et al., 2009). Thus some specimens with low viral titers will probably be undetected by using the rapid antigen test. 18 To overcome this sensitivity issue, a new rapid influenza A test, Flu A 19 Dot-ELISA was developed (Wantai Biological Pharmacy Enterprise company, 20 Beijing, China). This is a flow-through immunoassay that uses two influenza A virus 21 NP specific monoclonal antibodies (mAb). One of the antibodies, immobilized on a 22

Page 3 of 10

1	nitrocellulose membrane, serves as the capture antibody, and the other labeled with
2	horseradish peroxidase is used as the detecting antibody. The procedure involves
3	mixing 200µl of specimen with 400µl of lysis buffer. This mixture was filtered in a
4	microtiter-like well that had a permeable membrane located at the bottom of the well
5	with the antigen captured during the filtration process. The entire test procedure can
6	be completed in 30 minutes and the results can be read visually (Chen et al., 2008).
7	Four sets of experiments were conducted to determine the properties of this
8	assay. The first set of experiments was performed to compare the results of this kit
9	with another commercial kit, Quick Vue Flu A test (Quidel Corp., San Diego, CA)
10	against 10 strains of H5N1 influenza A viruses (Table 1). The detection limits of Flu A
11	Dot-ELISA for the different influenza A strains ranged log_{10} 2.4 to 4.8 TCID ₅₀ (or
12	0.002 to 0.025 HA), which was 80 times lower than the detection limits of Quick Vue
13	Flu A test. This sensitivity range is superior to many of the current rapid influenza
14	tests (CDC., 2009; Chan et al., 2009; Hurt et al., 2007).
15	The second set of experiments used 40 strains of influenza A virus isolated from
16	human, swine, avian, equine, and gull species and for controls, 26 strains of other
17	respiratory viruses including 18 strains of influenza B virus, two strains of human
18	parainfluenza viruses (HPIV), two strains of respiratory syncytial virus (RSV), two
19	strains of adenovirus, and two strains of Newcastle disease virus. The detection limits
20	for these influenza A strains ranged 0.01 to 0.001 HA units/0.2ml of sample, and there
21	was no difference for the limit of detection for the current influenza A H1N1 virus.
22	Another notable feature was the broad range of influenza A viruses detected from

Page 4 of 10

1	different host species. None of the 26 strains of non-influenza A respiratory virus
2	described above (data not shown) reacted positively to the test.
3	The third set of experiments evaluated the performance of Flu A Dot-ELISA
4	using nasal and throat swabs collected from patients in Southern China, and the
5	tracheal and cloacal swabs collected from apparently healthy chickens in live poultry
6	markets also in Southern China. Samples were tested in parallel by Flu A Dot-ELISA
7	and by virus culture in 10-day-old embryonated SPF chicken eggs or MDCK cells
8	(Chen et al., 2009). The sensitivity and specificity of Flu A Dot-ELISA for the human
9	samples were 88.5% (69/78) and 99.3% (146/147), respectively; and the positive
10	predictive and negative predictive values were 98.6% (69/70) and 94.2% (146/155),
11	respectively. For avian specimens, the sensitivity and specificity of Flu A Dot-ELISA
12	for the chicken samples were 88.1% (74/84) and 96.5% (83/86), respectively; and the
13	positive predictive and negative predictive values were 96.1% (74/77) and 89.2%
14	(83/93), respectively (Table 2).
15	The final set of experiments was an evaluation conducted in a cohort of real-time
16	RT-PCR confirmed novel influenza A / H1N1 pharyngeal specimens obtained from
17	hospitalized patients. The sensitivity was 94.5 (69/73, 95% CI: 85.8% to 98.2%).
18	These results show that the Flu A Dot-ELISA is highly sensitive and sufficiently
19	specific against all the variants of influenza A virus examined. As the test can be
20	accomplished rapidly and does not require extensive laboratory facilities, this may
21	play a role for rapid diagnosis of influenza A virus.
