2
3 Nogo-A, a major myelin inhibitory protein, inhibits axon growth and synaptic
4
5
6 function in the central nervous system. Glaucoma is a progressive neuropathy as a
7
8
9 result of retinal ganglion cell (RGC) death. Synaptic degeneration is thought to be an
10
11
12 early pathology of neurodegeneration in glaucoma and precedes RGC loss. Here
13
14 experimental ocular hypertension model was induced in adult rats with laser
15
16
17 coagulation of the episcleral and limbal veins. The expression of Nogo-A,
18
19
20 myelin-associated glycoprotein (MAG) and oligodendrocyte myelin glycoprotein
21
22 (OMgp) in the retina was investigated using immunohistochemistry and Western
23
24
25 blotting. We found that Nogo-A was expressed in the RGCs and upregulated after the
26
27
28 induction of ocular hypertension. OMgp was only expressed in the inner plexiform
29
30
31 layer. There was no MAG expression in the retina. Our data provided, for the first
32
33
34 time, the expression patterns of three myelin protein in the adult retina and suggested
35
36
37 an important role of Nogo-A in the RGC death and synaptic degeneration in
38
39 glaucoma.

Introduction

Glaucoma is a neurodegenerative disease characterized by the degeneration of retinal ganglion cells (RGCs) and their axons. Increasing evidence also supports the presence of compartmentalized degeneration in the synapses [1-3] and may underlie visual functional deficits in glaucoma. We previously identified that there is synaptic degeneration for RGCs in an ocular hypertension model of glaucoma and it may precede the RGC death [4]. These findings suggest that the synapse destruction could contribute significantly to the progressive nature of vision loss in glaucoma. Devising ways to induce such a reversal could represent an effective potential approach to neuroprotection.

The failure of axonal regeneration within the damaged adult central nervous system (CNS) has been ascribed in part to the presence of Nogo-A[5] myelin-associated glycoprotein (MAG) [6] and oligodendrocyte myelin glycoprotein (OMgp) [7,8]. All three bind the Nogo66 receptor (NgR1) [9] and the paired immunoglobulin-like receptor B (PirB) [10] to mediate their inhibitory influence. Although Nogo-A is thought to be the primary source of the Nogo related limitation of neuronal outgrowth after injury [5,11], much data demonstrates that Nogo-A is expressed by many populations of neurons in the CNS, and is not limited to oligodendrocytes [12-15]. Nogo-A expression was increased in the cortical neurons [16] and anti-Nogo-A antibody improves functional recovery in adult rats after stroke [17]. Nogo protein was detected in the retina of mouse embryos [18] and in the neonatal rat [19]. Neuronal Nogo-A may be involved in normal cell-functioning

1 separate from the post injury outgrowth-inhibitory role observed for oligodendroglial
2
3 Nogo-A[15]. Nogo-A plays a role in the maintenance of inhibitory synapses in
4
5 cerebellar Purkinje cells [20] and motor neuron in amyotrophic lateral sclerosis (ALS)
6
7 [21]. Unlike Nogo-A, MAG is not expressed in neurons but in glia of CNS and
8
9 peripheral nerves [22]. OMgp was first identified as a myelin protein but has
10
11 subsequently been found to be expressed on some neurons in the CNS [23]. However,
12
13 there were no reports for Nogo-A, MAG and OMgp in the retina of adult animals and
14
15 in glaucoma. In this study, we provide evidence that Nogo-A, but not OMgp and
16
17 MAG protein increased in the retina in an ocular hypertension model in rats. High
18
19 levels of Nogo-A may be a possible mechanism of the RGC death and synapse
20
21 degeneration in the glaucoma.

34 **Experimental Procedure**

35 **Animals**

36
37 Animal experiments were approved by the University of Hong Kong Faculty
38
39 Committee on the Use of Live Animals in Teaching and Research. Twenty two adult
40
41 female Sprague-Dawley (SD) rats (starting weight, 250-280 g) were used for the study.
42
43 The animals were anesthetized with intraperitoneal injection of ketamine (80 mg/kg)
44
45 and xylazine (8 mg/kg) during the experiments and were euthanized at the end of the
46
47 experiment with an overdose of pentobarbital sodium (150 mg/kg). Alcaine 0.5%
48
49 (Alcon-Couvreur, Belgium) was applied to the eyes before all operations and
50
51 antiseptic eye drops (Tobrex [Tobramycin 0.3%], Alcon-Couvreur, Belgium) were

8 9 **Induction of experimental ocular hypertension**

10
11 Argon laser (Ultima 2000SE Argon Laser, Coherent, Palo Alto, CA) was used to
12
13 coagulate the limbal and episcleral veins in the right eye of the rats. This technique
14
15 was adopted from the method by WoldeMussie et al [24] and has been adopted in our
16
17 laboratory for the retina degeneration and therapeutic effects on retina functions
18
19 [4,25-27]. About 90 spots were applied on the three episcleral veins and 70 spots on
20
21 the limbal vein (270° around the limbus, except on the nasal side) with the following
22
23 settings: power of 1000 mW; spot size of 50 µm in diameter; and duration of 0.1s. A
24
25 secondary laser surgery was performed to coagulate the reconnected blood vessel
26
27 seven days later. The intraocular pressure (IOP) of the eyes were measured using a
28
29 Tonopen XL Tonometer. Fluorogold (FG) labeling of RGCs was performed 7 days
30
31 before sacrifice. Both superior colliculi (SC) were exposed after removing a small
32
33 piece of skull and cortex, and a piece of Gelfoam (Pharmacia & Upjohn, Kalamozoo,
34
35 MI, USA) soaked with FG (6% in distilled H₂O, Fluorochrome, Denver, CO, USA)
36
37 was placed on the surface of SC. Rats were euthanized with an overdose of anesthesia

62 63 **Immunohistochemistry of Nogo-A, MAG, OMgp**

64
65 The animals were euthanized with an overdose of anesthesia at 0, 2 and 4 weeks after

1 the first laser coagulation. The eyes were enucleated following transcardial perfusion
2
3 with 0.9% saline and were fixed in 4% PFA for 1 h. After removing the corneas and
4
5 lens, the eye cups were fixed further in PFA for 4 h and then transferred to 30%
6
7 sucrose solution at 4°C for 16 h. Ten-micron-thick frozen retinal sections were washed
8
9 in 0.01M phosphate buffered saline (PBS) and were incubated in 0.5% Triton/PBS for
10
11 10 min. After being blocked with 10% normal goat serum for 1 h, the sections were
12
13 incubated with rabbit anti-Nogo-A (1: 100, CalBioChem, CA, USA), mouse
14
15 anti-MAG (1:100, Chemicon, Hofheim, Germany) and mouse anti-OMgp (1:100,
16
17 Chemicon, Hofheim, Germany) antibodies at 4°C for 16 h. Sections then were washed
18
19 with PBS three times and incubated with Alexa Fluor® 488 goat anti-rabbit second
20
21 antibody (1:400, Molecular probes, Oregon, USA) at room temperature for 2 h.
22
23 Negative control was performed on the retina sections at 2 weeks after the induction
24
25 of ocular hypertension with only incubation of Alexa Fluor® 488 goat anti-rabbit
26
27 second antibody. The positive control for Nogo-A was performed by staining Nogo-A
28
29 in the optic nerve from normal retina in the adult rat. The sections were analyzed
30
31 under Olympus IX71 fluorescent microscope with DP2-BSW software (Olympus,
32
33 Japan). Six animals were used in each group.

50 **Western Blotting for Nogo-A**

51
52 To measure Nogo-A in the retina, the animals were euthanized at 0, 5 days, 2 and 4
53
54 weeks after laser coagulation. The retinas were dissected and homogenized in lysis
55
56 buffer (10 mM Tris pH7.4, 150 mM NaCl, 1 mM EDTA, 1 mM EGTA) supplemented
57
58
59

64
65

1 with 10% protease inhibitor cocktail and 1% phosphatase inhibitor cocktails from
2
3 Sigma. Following centrifugation at 13,000 rpm for 30 min to remove cell debris, the
4
5 protein concentration of the supernatant was measured using a Bio-Rad DC protein
6
7 Assay Kit (Bio-Rad Laboratories, CA, USA). A 40-80 μ g aliquot of proteins from
8
9 each sample was subjected to 6% (for Nogo-A) or 10% (for β -actin)
10
11 SDS-polyacrylamide gel electrophoresis and transferred onto PVDF membrane. The
12
13 membranes were blocked with Odyssey blocking buffer (LI-COR, Inc., lincoln , NE,
14
15 USA) for 1 h in room temperature. Incubation with goat anti-Nogo-A (1:100, Santa
16
17 Cruz Biotechnology, CA, USA) antibody was performed for 16 h at 4°C. After
18
19 washing, the membranes were incubated with IRDye 800CW goat anti-mouse
20
21 secondary antibody (1:2000, LI-COR, Inc., lincoln , NE, USA) in Odyssey blocking
22
23 buffer for 1 h at room temperature. Protein loading was controlled using a mouse
24
25 antibody against anti-actin (1:2000, Chemicon, Hofheim, Germany) and finally
26
27 incubated with IRDye 800 goat anti-mouse secondary antibody (1:2000, LI-COR, Inc.,
28
29 lincoln , NE, USA). The membranes were scanned and analyzed using Odyssey
30
31 Infrared Imaging System (LI-COR, Inc., lincoln , NE, USA). All experiments for
32
33 Western blotting were performed with 5 animals in each group and repeated 3 times.

3 Illinois, USA).
4
5

6 **Results**

7 **Nogo-A expression in the normal rat retina**

8
9 The expression of Nogo-A in the retina was evaluated using immunohistochemistry.
10
11 Negative control only with second antibody showed no positive staining in the retina
12
13 at 2 weeks after ocular hypertension (Fig. 1a-b). Nogo-A was reported to express in
14
15 the oligodendrocytes. Here we found strong immunostaining for Nogo-A in the optic
16
17 nerve with myelin sheath of normal adult rat (Fig. 1c). Nogo-A positive staining was
18
19 visible mainly in the ganglion cell layer (GCL) and the nerve fiber layer (NFL) in the
20
21 normal retina (Fig.1d-f). Less immunoreactive staining was observed in the other
22
23 layers. Next we examined whether RGCs expressed Nogo-A. The retrograde FG
24
25 staining for RGCs was mainly distributed in the cytoplasm. Here we identified that
26
27 Nogo-A was expressed in the FG-labeled RGCs (Fig. 1j-l). Some Nogo-A positive
28
29 cells in GCL were not FG-labeled RGCs. Since amacrine cells are the other major
30
31 types of cells in the GCL, amacrine cells in GCL may also express Nogo-A protein.

37
38
39
40
41
42
43
44
45
46

47 **Increased Nogo-A expression after the induction of ocular hypertension**

48
49 We induced an ocular hypertension model in adult rats. Similar to our previous reports,
50
51 the IOPs were found to be 23.45 ± 0.79 mmHg and 24.32 ± 0.82 , respectively, in the
52
53 glaucomatous eyes at 2 weeks and 4 weeks after laser treatments, and 13.24 ± 0.46
54
55 mmHg in the normal eyes ($P < 0.01$). In the glaucomatous retina, high levels of
56
57
58
59
60
61

1 Nogo-A was detected in the RGCs. Strong Nogo-A immunostaining was found in the
2
3 inner plexiform layer (IPL) and outer nuclear layer (ONL) (Fig. 1g-i, m-o). This was
4
5 confirmed using Western blotting. Nogo-A expression increased at 5 days after IOP
6
7 elevation and there was up to 3 fold increase of the Nogo-A protein at 2 and 4 weeks
8
9 (Fig. 2, $P < 0.05$ compared to normal retina). No difference was found for the Nogo-A
10
11 levels between 2 weeks and 4 weeks ($P > 0.05$).
12
13
14
15
16
17
18
19

20 **MAG and OMgp expression after the induction of ocular hypertension**

21 We further examined the expression of the other two myelin proteins in the retina.
22
23 MAG protein was not detected in the retinas of normal and glaucomatous animals
24
25 (Fig. 3a). FG-labeled RGCs did not express MAG protein. No MAG expression was
26
27 found in the beginning portion of the optic nerve without myelin sheath. MAG was
28
29 only observed in the part of the optic nerve with myelin sheath (Fig. 3a). There was a
30
31 clear ridge for MAG expression in the longitudinal section of the optic nerve with the
32
33 optic disk. We further identified that there was low level of OMgp in the IPL in the
34
35 normal retina using immunohistochemistry (Fig. 3b). There was no OMgp
36
37 immunostaining in the FG-labeled RGCs (Fig. 3b). No difference was found for
38
39 OMgp protein in the retina before and after the induction of ocular hypertension (Fig.
40
41 3b).

56 **Discussion**

57 Here we demonstrated that Nogo-A was expressed in the normal retina and was
58
59
60
61
62
63
64
65

1 increased in a rat glaucoma model. We further identified that RGCs expressed
2
3 Nogo-A. There was no MAG expression in the retina and OMgp was only expressed
4
5
6 in the IPL. It is the first report about the expression of three myelin proteins in the
7
8
9 adult retina and in a rat model of ocular hypertension. The data suggest an important
10
11
12 role of Nogo-A in the normal retina and after ocular hypertension.
13

14 Glaucoma is a common eye disease that can cause irreversible loss of vision if
15
16 left undiagnosed and untreated. Compartmentalized degeneration in the synapses may
17
18
19 underlie visual functional deficits in glaucoma [1-3]. Early changes in RGC dendrites
20
21
22 have critical consequences on synaptic efficacy and may underlie functional deficits
23
24
25 in glaucoma [28-30]. The loss of visual sensitivity in the early stages of
26
27
28 experimentally induced glaucoma could be attributed to a loss of connectivity
29
30
31 secondary to synaptic degeneration [1]. We previously identified that synaptic
32
33
34 degeneration for RGCs may precede the RGC death in an ocular hypertension model
35
36
37 [4]. However, it is unclear for the mechanisms for the synaptic degeneration in
38
39
40 glaucoma. The model used in this study mimics the slow, progressive neuropathy
41
42
43 produced by elevated IOP in humans by partially obstructing aqueous humor outflow,
44
45
46 similar to elevated episcleral venous pressure glaucoma. However, there are still some
47
48
49 differences between this animal model and human glaucoma disease. Human chronic
50
51
52 glaucoma is a progressive optic neuropathy characterized by slow visual field loss
53
54
55 with a long-term-even several decades long-course, whereas there was significant
56
57
58 RGC loss in several weeks in this rat ocular hypertension mode. Even so, the finding
59
60
61 of increased Nogo-A expression partly indicates that the Nogo-A may play some role
62
63
64
65

1 for vision loss in the human glaucoma.

2
3 Previous opinions for myelin proteins are that they are limited to
4 oligodendrocytes. However, much current data demonstrate that Nogo-A is expressed
5
6 in many populations of neurons in the CNS. Our findings of the expression of Nogo-A
7
8 in the RGCs in rats is consistent with previous reports that Nogo-A is expressed in the
9
10 embryo or neonatal animals [18,19]. Besides the inhibition of axonal regeneration or
11
12 neurite outgrowth, Nogo-A plays an important role in synapse maintenance and neural
13
14 survival. Nogo-A genetic deletion resulted in prolonged cell survival in addition to
15
16 axonal regeneration in mice with amyotrophic lateral sclerosis [31]. Nogo-A could
17
18 signal transsynaptically as observed e.g. for Ephrins to regulate synapse maintenance
19
20 [32-34]. The reduction of Nogo-A expression in the cell-Deep Cerebellar Nuclei
21
22 correlates with synapse maturation [20]. The upregulation of Nogo-A in our model is
23
24 consistent with previous reports about the increased expression of Nogo-A in
25
26 Alzheimer disease [35], in muscles and spinal cord motoneurons of amyotrophic
27
28 lateral sclerosis [36]. The increased expression of Nogo-A may be a primary factor
29
30 leading to the synaptic function deficits and further RGC death. It is interesting that
31
32 we found increased Nogo-A expression at 5 days after IOP elevation. We previously
33
34 identified that there was significant synaptic degeneration but no RGC loss at 5 days
35
36 in this ocular hypertension model [4]. The early upregulation of Nogo-A provide
37
38 further evidence that Nogo-A may firstly affect synaptic function and then lead to the
39
40 secondary RGC death. Furthermore, our data showed that there was no difference for
41
42 Nogo-A levels at 2 weeks and 4 weeks after IOP elevation. It suggests that Nogo-A
43
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60
61
62
63
64
65

1 protein reaches a saturation under the balance of production and cleaning. In this
2
3 model, RGC loss stabilizes after 4 weeks [37]. The stability of Nogo-A accumulation
4
5
6 after 2 weeks may has some relationship with the stabilization of RGC loss.
7

8
9 Our study indicates that some amacrine cells may also express Nogo-A.
10
11 Amacrine cells in the vertebrate retina are interneurons that interact at the second
12
13 synaptic level in the pathways consisting of the photoreceptor-bipolar-ganglion cell
14
15 chain. They are synaptically active and serve to integrate, modulate and interpose a
16
17 temporal domain to the visual message presented to the ganglion cell. The expression
18
19 of Nogo-A in amacrine cells may be one of stations of Nogo-A to affect the synaptic
20
21 function.
22
23
24
25
26

27
28 LINGO-1 (LRR and Ig domain-containing, Nogo Receptor-interacting protein-1)
29
30 [38] was a member of NgR1 signaling complexes that prevent axonal regeneration in
31
32 the presence of three myelin inhibitors. Because NgR1 is a GPI anchored protein,
33
34 LINGO-1 and the other co-receptors, p75/TROY transduce the myelin inhibitory
35
36 signal into the cells. We found that blocking LINGO-1 function promotes survival of
37
38 damaged RGCs in a chronic adult rat ocular hypertension model [25]. The
39
40 upregulation expression of Nogo-A after IOP elevation provides a possibility that
41
42 LINGO-1 antagonists disturb the function of Nogo-A and NgR1, and then exert the
43
44 neuroprotection. It may be one of the mechanisms how LINGO-1 antagonist promotes
45
46 RGC survival.
47
48
49
50
51
52
53

54
55 In this study, we found that Nogo-A, but not OMgp and MAG protein increased
56
57 in the retina after ocular hypertension. It may provide a possible mechanism
58
59
60
61

1 underlying the synapse degeneration and RGC death in glaucoma.

Figure Legends

Figure 1 Immunohistochemistry of Nogo-A in the normal and ocular

hypertensive retina. (a) Negative control for Nogo-A expression in the retina at 2 weeks after ocular hypertension. (b) The same visual field showed fluorogold labeled retinal ganglion cells in (a). (c) Nogo-A expression in the optic nerve in adult rat as positive control. Nogo-A was expressed in the ganglion cell layer in the normal retina (d, j). Retinal ganglion cells (RGCs) expressed Nogo-A (white arrow heads) (j-l). Some Nogo-A positive cells in the GCL were not FG-labeled RGCs (white arrows). Strong Nogo-A expression was found in RGCs (white arrow heads and red arrows), especially for RGCs in the GCL, in the IPL and INL at 2 weeks after ocular hypertension (m-o). The pictures in the boxes in i-l and m-o were enlarged below. Nogo-A staining (green); FG-labeled RGCs (blue); merge of Nogo-A and FG labeling (orange). We regarded red as the color of FG in the picture of merge. GCL, ganglion cell layer; INL, inner nuclear layer; ONL, outer nuclear layer; FG, fluorogold.

Figure 2 Western blot of Nogo-A in the normal and ocular hypertension retinas.

Nogo-A expression in the normal and injured eyes with Western blotting and densitometric analysis of Western blot analysis ($P < 0.05$, compared with normal retina). $n = 5$ animals per group.

Figure 3 The expression of Myelin associated glycoprotein (MAG) and

oligodendrocyte myelin glycoprotein (OMgp) in glaucoma. (a) MAG expression.

1 (a1) Normal retina; (a2) The retina after 2 weeks of ocular hypertension. (a3) optic
2
3 disc in the normal retina. There was no expression of MAG in the normal retinas (a1)
4
5 and after the induction of ocular hypertension (a2). MAG was expressed in the optic
6
7 nerve with myelin sheaths (a3, upper picture: light microscopy picture to show the
8
9 optic disc structure). (b) OMgp expression. (b1) Normal retina; (b2) The retina after 2
10
11 weeks of ocular hypertension. There was moderate expression of OMgp in the NFL,
12
13 GCL, IPL and INL in the normal retinas (b1). OMgp expression had no change at 2
14
15 weeks after the induction of ocular hypertension (b2). MAG or OMgp staining (green);
16
17 FG-labeled RGCs (blue); We regarded red as the color of FG in the merged picture.
18
19 NFL: nerve fiber layer; GCL, ganglion cell layer; INL, inner nuclear layer; ONL,
20
21 outer nuclear layer; FG, fluorogold. $n = 5$ animals per group. Bar = 25 μm .
