On Lagrange's four squares theorem with almost prime variables

By *Kai-Man Tsang* at Hong Kong and *Lilu Zhao* at Hefei

Abstract. In 1994, Brüdern and Fouvry [1] initiated the investigation of Lagrange's four squares theorem with almost prime variables. In this paper, we prove that every sufficiently large integer, congruent to 4 modulo 24, can be represented as a sum of four squares of integers, each of which has at most four prime factors. Instead of the four-dimensional vector sieve developed by Brüdern and Fouvry [1], we establish this result by combining the threedimensional sieve and the switching principle.

1. Introduction

We consider the equation of Lagrange

$$
(1.1)\t\t\t x_1^2 + x_2^2 + x_3^2 + x_4^2 = N
$$

with multiplicative restrictions. It is expected that sufficiently large integers under certain necessary congruence condition can be written as sums of four squares of primes. This problem has not been solved so far. However Hua [10] proved that all large integers congruent to 5 modulo 24 are sums of five squares of primes by using Vinogradov's method for the ternary Goldbach problem.

Kloosterman [11] developed the circle method to study the asymptotic formula for the number of integer solutions of the following positive definite quadratic forms

$$
a_1x_1^2 + a_2x_2^2 + a_3x_3^2 + a_4x_4^2 = N.
$$

Estermann [5] investigated the indefinite quadratic forms via the circle method and the Kloosterman refinement. The classical circle method with mean value theorems (see [16] for the exposition) provides an asymptotic formula for quadratic forms with five or more variables only.

The work described in this paper was substantially supported by a grant from the Research Grants Council of the Hong Kong Special Administrative Region, China (HKU 705610P). The second author is also supported by the National Natural Science Foundation of China (Grant No. 11401154).

Greaves [6] considered the solutions of (1.1) with two prime and two integral variables. Plaksin [12] and Shields [14] obtained an asymptotic formula for the number of solutions. Podsypanin [13] derived an asymptotic formula for the number of solutions of (1.1) in which x_1, x_2, x_3, x_4 are square-free.

In 1994, Brüdern and Fouvry [1] established that every sufficiently large integer, congruent to 4 modulo 24, can be written as the sum of four squares of integers, each of which has at most 34 prime factors.

In 2003, Heath-Brown and Tolev [9] managed to solve the equation

$$
(1.2) \t\t\t p^2 + x_1^2 + x_2^2 + x_3^2 = N
$$

with multiplicative restrictions, where p denotes a prime number. Precisely, they established the solvability of (1.2) with each of x_i having at most 101 prime divisors. This was improved by Tolev [15] who showed that 101 can be replaced by 80, and then improved by Cai [3] who showed that 42 is acceptable. Our first result is as follows.

Theorem 1.1. *Every sufficiently large integer* N*, congruent to* 4 *modulo* 24*, can be represented in the form of*

(1.3) $N = p^2 + x_1^2 + x_2^2 + x_3^2$,

where p is a prime and each of x_1 , x_2 , x_3 *has at most five prime factors.*

As in [9], the proof of the above theorem will be finished in two steps. In the first step, we combine the circle method with Kloosterman refinement and the square sieve to control the reminder term uniformly for certain level D. In the second step, we use the sieve method to produce the almost primes. For the uniform estimate, we shall develop the strategy of Heath-Brown and Tolev, and push their method further.

Comparing to the proof in [9], two things are different. We start from applying Cauchy's inequality for summation over k only rather than summations over k and d (see (5.2) in Section 5). This subtle difference contributes to a better result because it can be proved that the error term is dominated by diagonal contributions up to P^{ε} (see Lemma 12 below). To this end, we have to introduce the condition (2.8) at the beginning, and then we remove it before we close the proof. This obstacle is one of the reasons that force Brüdern and Fouvry to develop the vector sieve (cf. the discussion in [1, Section III]). Finally instead of the vector sieve which was used by Brüdern and Fouvry, and by Heath-Brown and Tolev, we appeal to the switching principle of Chen [4] to reduce the number of prime factors for each variable.

The square sieve of Heath-Brown [8] plays an important role in the proof. However we will choose the parameter R to be of type P^{ε} . Therefore, the square sieve is really responsible for the success of the proof, while it does not determine the quality of the level D.

Concerning the Lagrange equation with four almost prime variables, the value 34 due to Brüdern and Fouvry was sharpened by Heath-Brown and Tolev [9] to 25, by Tolev [15] to 20, and by Cai [3] to 13. We shall prove the following result.

Theorem 1.2. *Every sufficiently large integer* N*, congruent to* 4 *modulo* 24*, can be represented in the form of*

(1.4) $N = x_1^2 + x_2^2 + x_3^2 + x_4^2$,

where each of x_1 , x_2 , x_3 , x_4 *has at most four prime factors.*

In prior works [1, 9], in order to obtain a sharp result involving four almost prime variables, people considered the equation

$$
N = d_1^2 x_1^2 + d_2^2 x_2^2 + d_3^2 x_3^2 + d_4^2 x_4^2.
$$

Our approach to Theorem 1.2 is different. We consider the equation

$$
N = q^2 + d_1^2 x_1^2 + d_2^2 x_2^2 + d_3^2 x_3^2,
$$

where q is an almost prime. Therefore, instead of the vector sieve developed by Brüdern and Fouvry [1], we shall combine the three-dimensional sieve and the switching principle to establish Theorem 1.2.

As usual, we write $e(z)$ for $e^{2\pi i z}$. We use ε to denote a sufficiently small positive number, and the letter A denotes a sufficiently large constant. We use \ll to denote Vinogradov's well-know notation, while implicit constants may depend on ε and A.

2. A crucial proposition

Before giving the main propositions, we introduce some notations. Let N be a sufficiently large integer satisfying $N \equiv 4 \pmod{24}$. Set $P = N^{1/2}$. The letter p is reserved for prime numbers. As usual, $\mu(n)$, $\phi(n)$ and $\tau(n)$ denote the Möbius function, Euler's totient function, and the divisor function respectively. For the natural number q and real number α , we write $e_q(\alpha) = e(\alpha/q)$. We use $\sum_{x(q)}$ and $\sum_{x(q)^*}$ to denote sums with x running over a complete system, respectively reduced system of residues modulo q. The Gauss sums $S(q, m, n)$ and $T(q, a)$ are defined by

(2.1)
$$
S(q, m, n) = \sum_{x(q)} e_q(mx^2 + nx), \quad S(q, m) = S(q, m, 0),
$$

$$
T(q, a) = \sum_{x(q)^*} e_q(ax^2),
$$

and

$$
S_{\mathbf{d}}(q,m,\mathbf{n}) = \prod_{j=1}^{3} S(q, md_j^2, n_j), \quad S_{\mathbf{d}}(q,m) = S_{\mathbf{d}}(q,m,\mathbf{0}),
$$

where we use the bold style letter **d** to indicate the three-dimensional vectors (d_1, d_2, d_3) . Now we define the singular series

(2.2)
$$
\Sigma_0(\mathbf{d}, N) = \sum_{q=1}^{\infty} h_{\mathbf{d}}(q) = \prod_{p>2} (1 + h_{\mathbf{d}}(p)),
$$

where

$$
h_{\mathbf{d}}(q) = q^{-3} \phi(q)^{-1} \sum_{a(q)^*} S_{\mathbf{d}}(q, a) T(q, a) e_q(-aN).
$$

Let

$$
\omega_0(t) = \begin{cases} \exp(\frac{1}{(20t - 10)^2 - 1}) & \text{if } \frac{9}{20} < t < \frac{11}{20}, \\ 0 & \text{otherwise}, \end{cases}
$$

and denote

$$
\omega(x) = \omega_0(xP^{-1}), \quad \omega(\mathbf{x}) = \prod_{j=1}^3 \omega(x_j).
$$

We define

$$
I(\beta, u) = \int_{-\infty}^{+\infty} \omega_0(x) e(\beta x^2 + ux) dx, \quad I(\beta) = I(\beta, 0),
$$

and

$$
I_{\mathbf{d}}(\beta, \mathbf{u}) = \prod_{j=1}^{3} I(\beta, u_j d_j^{-1}).
$$

Let

(2.3)
$$
H(t) = \int_{-\infty}^{+\infty} I^3(\beta) e(-t\beta) d\beta.
$$

For any $j \le 15$, let A_j denote the set consisting of integers $q \le P$ satisfying two restrictions:

- (i) the number of prime factors of q counting multiplicity is exactly j ,
- (ii) all prime factors of q are greater than $P^{1/16}$.

In order to apply the sieve method, we study

(2.4)
$$
\mathcal{L}_{d}(N) := \mathcal{L}_{d}^{j}(N) = \sum_{\substack{q^{2}+x_{1}^{2}+x_{2}^{2}+x_{3}^{2}=N \ q \in \mathcal{A}_{j}, d_{i} \mid x_{i} \ (1 \leq i \leq 3)}} \omega(q)\omega(\mathbf{x}).
$$

Here we also attach the smooth weight $\omega(q)$ for the use of switching principle. The corresponding singular integral is defined by

(2.5)
$$
\mathcal{N}_0(N) := \mathcal{N}_0^j(N) = P \int_0^P H\left(1 - \frac{x^2}{P^2}\right) \frac{\omega(x) C_j(x) dx}{\log x},
$$

where $C_1(x) = 1$ and for $j \ge 2$,

$$
C_j(x) = \sum_{p^{1/16} < p_1 \leq \cdots \leq p_{j-1} \leq (x p_1^{-1} \cdots p_{j-2}^{-1})^{1/2}} \frac{\log x}{(\log x - \log (p_1 \cdots p_{j-1})) p_1 \cdots p_{j-1}}.
$$

The expected main term for $\mathcal{L}_{d}(N)$ is $\mathcal{N}_{0}(N)\Sigma_{0}(\mathbf{d}, N)(d_1d_2d_3)^{-1}$. (Here and after, we shall often suppress the dependence on j when the meaning is clear from the context.) We plan to investigate

$$
\mathcal{H}(D) = \sum_{\substack{d_1, d_2, d_3\\[d_1, d_2, d_3] \le D}} \beta(\mathbf{d}) \bigg(\mathcal{L}_{\mathbf{d}}(N) - \frac{\mathcal{N}_0(N) \Sigma_0(\mathbf{d}, N)}{d_1 d_2 d_3} \bigg),
$$

where $\beta(\mathbf{d}) = \beta(d_1, d_2, d_3)$ is a real function satisfying

(2.6)
$$
|\beta(\mathbf{d})| \le \tau^2 (d_1) \tau^2 (d_2) \tau^2 (d_3),
$$

and β (**d**) = 0 unless

(2.7)
$$
\mu(2d_1)\mu(2d_2)\mu(2d_3) \neq 0.
$$

Let

$$
\mathcal{H}_0(D) = \sum_{d_1, d_2, d_3 \le D} \beta(\mathbf{d}) \bigg(\mathcal{L}_\mathbf{d}(N) - \frac{\mathcal{N}_0(N) \Sigma_0(\mathbf{d}, N)}{d_1 d_2 d_3} \bigg).
$$

Heath-Brown and Tolev established the following result.

Proposition 1 ([9]). If
$$
D = P^{2/69-\varepsilon}
$$
, then one has

$$
\mathcal{H}_0(D) \ll P^2 (\log P)^{-A}.
$$

Define

$$
B(d_1, d_2, d_3, d_4, N) = \sum_{\substack{x_1^2 + x_2^2 + x_3^2 + x_4^2 = N \\ x_i \equiv 0 \pmod{d_i}}} \prod_{i=1}^4 \omega(x_i)
$$

and

$$
\Sigma_1(d_1, d_2, d_3, d_4, N) = \sum_{q=1}^{\infty} q^{-4} \sum_{a(q)^*} e_q(-aN) \prod_{i=1}^4 S(q, ad_i^2).
$$

Let

$$
\mathcal{H}_0^*(D) = \sum_{d_1, d_2, d_3, d_4 \le D} \left| B(d_1, d_2, d_3, d_4, N) - \kappa_1 N \frac{\Sigma_1(d_1, d_2, d_3, d_4, N)}{d_1 d_2 d_3 d_4} \right|,
$$

where the constant κ_1 is given by

$$
\kappa_1 = \int_{-\infty}^{\infty} I^4(\beta) e(-\beta) d\beta.
$$

It was proved by Heath-Brown and Tolev that:

Proposition 2 ([9]). If
$$
D \leq P^{1/8-\varepsilon}
$$
, then one has
 $\mathcal{H}_0^*(D) \ll P^{2-\varepsilon}$.

Proposition 2 improves upon the result of Brüdern and Fouvry [1] who essentially showed $\mathcal{H}_0^*(D) \ll P^{2-\varepsilon}$ provided that $D \leq P^{1/11-\varepsilon}$.

Concerning $H(D)$, we prove the following result.

Proposition 3. Suppose that $D < P^{1/2-\epsilon}$. Then we have $\mathcal{H}(D) \ll P^2(\log P)^{-A}.$

Remark. (i) The function β (d) may depend on N, but in view of (2.6), the absolute value of β (**d**) is bounded from above by $\prod_{j=1}^{3} \tau^{2}(d_j)$ which is independent of N.

(ii) With the application to Lagrange's four squares theorem with almost prime variables in mind, Proposition 3 improves upon both Proposition 1 and Proposition 2.

In order to prove Proposition 1, Heath-Brown and Tolev investigated the following object:

$$
\Omega_{\mathbf{d}}(n) = \sum_{\substack{x_1^2 + x_2^2 + x_3^2 = n \\ d_j \mid x_j \ (1 \le j \le 3)}} \omega(\mathbf{x}).
$$

The application of circle method suggests that the sum $\Omega_d(n)$ may be approximated by

$$
\mathcal{M}_{\mathbf{d}, Q}(n) = \frac{PH(nN^{-1})}{d_1 d_2 d_3} \sum_{q \le Q} q^{-3} \sum_{a(q)^*} e_q(-an) S_{\mathbf{d}}(q, a).
$$

Consider

$$
\widetilde{\mathcal{E}}(D, Q) = \sum_{d_1, d_2, d_3 \le D} \tau(d_1) \tau(d_2) \tau(d_3) \sum_{k \le P} |\Omega_{\mathbf{d}}(N - k^2) - \mathcal{M}_{\mathbf{d}, Q}(N - k^2)|.
$$

Heath-Brown and Tolev established

$$
\widetilde{\mathcal{E}}(D, Q) \ll P^{2-\varepsilon}
$$

provided that $Q = P^{20/23}$ and $D = P^{2/69-10\varepsilon}$. Our purpose is to establish the following result.

Proposition 4. *Let*

$$
\mathcal{G}(n; Q, D_1, D_2, D_3) = \sum_{d_i \leq D_i} \beta(d_1, d_2, d_3) (\Omega_{\mathbf{d}}(n) - \mathcal{M}_{\mathbf{d}, Q}(n)),
$$

where $\beta(d_1, d_2, d_3)$ *satisfies* (2.6)*,* (2.7*) and*

$$
(2.8) \qquad (d_i, d_j) \le P^{\varepsilon} \quad \text{for } 1 \le i < j \le 3.
$$

Suppose that $D_1 D_2 D_3 < P^{1/2-6\varepsilon}$ and $P^{1-4\varepsilon} < Q < P^{1-2\varepsilon}$. Then we have

$$
\sum_{k\leq P} |\mathcal{G}(N-k^2; Q, D_1, D_2, D_3)| \ll P^{2-\varepsilon}.
$$

Proposition 4 will be proved in Sections 3–6. As an application of Proposition 4, we shall prove Proposition 3 in Section 7.

3. Basic assumptions

We first quote some lemmas which are well known.

Lemma 1. *The Gauss sum defined by* (2.1) *satisfies:*

(i) *If* $(q_1, q_2) = 1$ *, then*

$$
S(q_1q_2, a_1q_2 + a_2q_1, n) = S(q_1, a_1q_2^2, n)S(q_2, a_2q_1^2, n).
$$

(ii) *Suppose that* $(q, m) = k$ *. Then we have*

$$
S(q,m,n) = \begin{cases} kS(q/k,m/k,n/k) & if k | n, \\ 0 & otherwise. \end{cases}
$$

(iii) *If* $(q, 2m) = 1$ *, then*

$$
S(q,m,n) = e_q(-\overline{4m}n^2)\left(\frac{m}{q}\right)S(q,1),
$$

where \bar{x} *denotes the inverse of* x *modulo q.*

(iv) *If* q *is odd, then*

$$
S(q, 1) = \begin{cases} q^{1/2} & \text{if } q \equiv 1 \pmod{4}, \\ iq^{1/2} & \text{if } q \equiv 3 \pmod{4}. \end{cases}
$$

(v) *If* $(2, a) = 1$ *, then*

$$
|S(2^l, a, n)| \le 2^{1 + l/2}.
$$

(vi) For any odd integer q, we have $|\gamma(q)| \leq q^{1/2}$, where

$$
\gamma(q) = \sum_{x(q)^*} \left(\frac{x}{q}\right) e_q(x).
$$

Throughout, by $\left(\frac{l}{a}\right)$ $\frac{l}{q}$) we denote the Jacobi symbol.

Lemma 2. *Denote the Kloosterman sum by*

$$
K(p, m, n) = \sum_{x=1}^{p-1} e_p(mx + n\overline{x}).
$$

If $p \nmid (m, n)$ *, then*

$$
|K(p,m,n)| \leq 2p^{1/2}.
$$

Lemma 3. *Let* $c_q(n)$ *be the Ramanujan sum given by*

$$
c_q(n) = \sum_{x(q)^*} e_q(xn).
$$

Then we have

$$
|c_q(n)| \le (q, n).
$$

Lemma 4. *The following statements hold.*

(i) *Suppose that* $u = \max\{|u_1|, \ldots, |u_6|\} > 0$ *. Then we have*

$$
\int_{-\infty}^{+\infty} |I(\beta, u_1) \cdots I(\beta, u_6)| d\beta \ll \min\{1, u^{-2+\varepsilon}\}.
$$

(ii) *Suppose that* $\beta_0 > 0$ *. Then we have*

$$
\int_{|\beta| \ge \beta_0} |I(\beta)|^6 d\beta \ll \beta_0^{-2}.
$$

Lemma 4 is a consequence of [9, Lemma 9 and Lemma 10]. Let

$$
f_d(\alpha) = \sum_{\substack{x \in \mathbb{Z} \\ x \equiv 0 \pmod{d}}} \omega(x) e(\alpha x^2), \quad f_d(\alpha) = \prod_{i=1}^3 f_{d_i}(\alpha),
$$

and let

$$
\mathcal{W}_{\mathbf{d},Q}(\alpha) = \sum_{n \in \mathbb{Z}} \mathcal{M}_{\mathbf{d},Q}(n) e(\alpha n).
$$

The following two lemmas provide useful approximations to $f_d(\alpha)$ and $W_{d,Q}(\alpha)$ respectively.

Lemma 5 ([9, Lemma 12]). Let q, d, b, h $\in \mathbb{N}$, let $\beta \in \mathbb{R}$, $q \leq P$ with $|\beta| \leq (qP)^{-1}$ and $d, b \leq P^2$. Then we have

$$
f_d\left(\frac{h}{b} + \beta\right) = \frac{P}{bd} \sum_{|n| \le bdq^{-1}P^{\varepsilon}} S(b, hd^2, n)I\left(\beta N, -\frac{Pn}{bd}\right) + O(P^{-A}),
$$

where the implicit constant depends on A and ε *.*

Lemma 6 ([9, Lemma 16]). Suppose that $Q \leq P^{1-\epsilon}$, $|\beta| \leq (qP)^{-1}$ and $(a,q) = 1$. *Then we have*

$$
\mathcal{W}_{\mathbf{d},Q}(\alpha) = \begin{cases} \frac{P^3}{q^3 d_1 d_2 d_3} S_{\mathbf{d}}(q,a) I^3(\beta N) + O(P^{-A}) & \text{if } 1 \le q \le Q, \\ O(P^{-A}) & \text{if } Q < q \le P, \end{cases}
$$

where the implicit constants depend on A and ε *.*

Set

$$
\sigma_0 = \int_{-\infty}^{+\infty} |I^6(\beta)| d\beta.
$$

Lemma 7. *Let*

$$
B(\alpha) = \sum_{n \in \mathbb{Z}} H^2\bigg(\frac{n}{N}\bigg) e(n\alpha),
$$

where $H(t)$ *is given in* (2.3)*. We have*

$$
B(\alpha) = \begin{cases} \sigma_0 P^2 + O(P^{-A}) & \text{if } \alpha \in \mathbb{Z}, \\ O(P^{-A}) & \text{if } \|\alpha\| \ge P^{\varepsilon - 2}, \end{cases}
$$

where the implicit constants may depend on A and ε *.*

Lemma 7 is [9, formula (115)].

4. Some preparations

Let

(4.1)
$$
\theta(q; \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, v, b_1, b_2) = \sum_{a(q)^*} e_q(\overline{ab_1}v) S_{\mathbf{d}}(q, ab_2^2, \mathbf{n}) S_{\mathbf{t}}(q, -ab_1^2, -\mathbf{l}),
$$

and let

$$
(4.2) \quad \eta = \eta(\mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, v, b_1, b_2) = b_1^2 b_2^2 \left(-4 \frac{v}{b_1} + \sum_{\substack{j=1 \ n_j \neq 0}}^3 \frac{n_j^2}{d_j^2 b_2^2} - \sum_{\substack{i=1 \ i \neq 0}}^3 \frac{l_i^2}{t_i^2 b_1^2} \right) \times \text{lcm},
$$

where we use lcm to denote the least common multiple of d_i $(j \in J)$ and t_i $(i \in I)$ with the index sets $J = \{1 \le j \le 3 : n_j \ne 0\}$ and $I = \{1 \le i \le 3 : l_i \ne 0\}$. For $\mathbf{n} = \mathbf{l} = \mathbf{0} \in \mathbb{Z}^3$, we assume lcm $= 1$. For simplicity, in this section we always assume that **d** satisfies (2.7), (2.8) and $d_i \leq D_i$ for $1 \leq i \leq 3$, and we also have analogous assumptions with **t** in place of **d**. We use the notations $(q, \mathbf{k}) = (q, k_1)(q, k_2)(q, k_3)$ and $(q, \mathbf{k}^2) = (q, k_1^2)(q, k_2^2)(q, k_3^2)$ for $\mathbf{k} = \mathbf{d}$ and t.

Lemma 8. Let $\theta(q) := \theta(q; \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, v, b_1, b_2)$ be defined in formula (4.1). Suppose *that* $(2, r) = 1$ *and* $(b_1b_2, 2r) = 1$ *. Then we have*

$$
|\theta(2^u r)| \leq \begin{cases} 2^{4u+6} r^3(r,\eta)(r,\mathbf{d})(r,\mathbf{t}) & \text{if } \eta \neq 0 \text{ and } (\mathbf{n},\mathbf{l}) \neq \mathbf{0} \in \mathbb{Z}^6, \\ 2^{4u+6} r^4(r,\mathbf{d}^2)^{1/2}(r,\mathbf{t}^2)^{1/2} & \text{otherwise,} \end{cases}
$$

where $\eta = \eta(\mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, v, b_1, b_2)$ *is given by* (4.2)*.*

Proof. As a function of q , $\theta(q) = \theta(q; \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, v, b_1, b_2)$ is multiplicative. So it suffices to prove

(4.3)
$$
|\theta(2^u)| \le 2^{4u+6},
$$

and

(4.4)
$$
|\theta(p^{\alpha})| \leq \begin{cases} p^{3\alpha}(p^{\alpha}, \eta)(p^{\alpha}, \mathbf{d})(p^{\alpha}, \mathbf{t}) & \text{if } \eta \neq 0 \text{ and } (\mathbf{n}, \mathbf{l}) \neq \mathbf{0}, \\ p^{4\alpha}(p^{\alpha}, \mathbf{d}^2)^{1/2}(p^{\alpha}, \mathbf{t}^2)^{1/2} & \text{otherwise}, \end{cases}
$$

for odd prime p . Plainly, (4.3) follows from Lemma 1 (v). By Lemma 1 (ii) and (iii),

$$
S(p^{\alpha}, am^2, n) = \begin{cases} e(\frac{-4m^2an^2}{p^{\alpha}})S(p^{\alpha}, a) & \text{if } p \nmid m, \\ e(\frac{-4s^2at^2}{p^{\alpha-2}})p^2S(p^{\alpha-2}, a) & \text{if } p \mid m = ps, p^2 \mid n = p^2t \text{ and } \alpha \ge 2, \\ 0 & \text{if } p \mid m = ps, p^2 \nmid n \text{ and } \alpha \ge 2, \\ p & \text{if } p \mid m, p \mid n \text{ and } \alpha = 1, \\ 0 & \text{if } p \mid m, p \nmid n \text{ and } \alpha = 1, \end{cases}
$$

where p $\parallel m$ means p $\mid m$ but $p^2 \nmid m$. Then for $\alpha \geq 2$, we have

$$
(4.5) \quad \theta(p^{\alpha}) = \begin{cases} p^{\beta+3\alpha} \sum_{a(p^{\alpha})^*} e\left(\frac{\overline{ab_1}v}{p^{\alpha}}\right) e\left(-\overline{4a}\frac{h\overline{c}}{p^{\alpha}}\right) & \text{if } (p^{\alpha}, d_j^2) \mid n_j \text{ and} \\ 0 & \text{otherwise,} \end{cases}
$$

where $p^{\beta} \parallel d_1 d_2 d_3 t_1 t_2 t_3$ and

$$
\frac{h}{c} = \sum_{j=1}^{3} \left(\frac{n_j^2}{d_j^2 b_2^2} - \frac{l_j^2}{t_j^2 b_1^2} \right)
$$

with $(h, c) = 1$. This proves (4.4) in the case $\alpha \ge 2$ by using Lemma 3. Hence we turn to the case $\alpha = 1$.

If $p \nmid d_1d_2d_3t_1t_2t_3$, then formula (4.5) still holds for $\alpha = 1$. We therefore confine to the case $p \mid d_1 d_2 d_3 t_1 t_2 t_3$. Note that

$$
|S(p, am^2, n)| \le p^{1/2}(p, m)^{1/2}
$$

by Lemma 1 (ii), (iii) and (iv). The second estimate of (4.4) follows easily. Now we assume that $\eta \neq 0$ and $(n, l) \neq 0$. If p || $d_1 d_2 d_3 t_1 t_2 t_3$, then $\theta(p)$ is in the form

$$
\theta(p) = pS(p, 1)^5 \sum_{a(p)^*} \left(\frac{a}{p}\right) e\left(\frac{abc}{q}\right),
$$

where $(b, p) = 1$. The summation over a is either 0 or a Gauss sum. So, by Lemma 1 (vi), we have

$$
|\theta(p)| \le p^{3+1/2}(p, \mathbf{d})^{1/2}(p, \mathbf{t})^{1/2} = p^3(p, \mathbf{d})(p, \mathbf{t}).
$$

If $p^2 | d_1 d_2 d_3 t_1 t_2 t_3$, then we apply the trivial bound for summation over a to get

$$
|\theta(p)| \le p^4(p, \mathbf{d})^{1/2}(p, \mathbf{t})^{1/2} \le p^3(p, \mathbf{d})(p, \mathbf{t}).
$$

The proof is completed.

From now on, we assume that p, p' are two different primes satisfying $R \le p$, $p' < 2R$ and $(p p', d_1 d_2 d_3 t_1 t_2 t_3 N) = 1$. For $\Delta | (p p')^2$, we have the unique decomposition $\Delta = \delta \delta'$, where $(p, \delta') = (p', \delta) = 1$. We use π and π' to denote a power of p, and respectively a power of p' (note that π and π' may be equal to 1).

Let us define

$$
W(\Delta, q; \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, p, p', v) = \sum_{s(pp')^*} \left(\frac{s}{pp'}\right) e_{pp'}(-sN) \sum_{\substack{a(q)^*\\ (app'+sq, qpp')=\Delta}} e_q(\overline{a}v)
$$

$$
\times S_{\mathbf{d}}(app'\Delta^{-1}, (app' + sq)\Delta^{-1}, \mathbf{n}) S_{\mathbf{t}}(q, -a, -\mathbf{l})
$$

and

$$
\mathcal{R}(\delta, p, \pi; \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, m_1, m_2, n) = \sum_{c(p)^*} \left(\frac{c}{p}\right) e_p(-cn) \sum_{\substack{b(\pi)^* \\ (bp+c\pi, \pi p)=\delta}} e_{\pi}(\overline{bm_1}v)
$$

$$
\times S_{\mathbf{d}}\left(\frac{\pi p}{\delta}, \frac{bp+c\pi}{\delta}m_2^2, \mathbf{n}\right) S_{\mathbf{t}}(\pi, -bm_1^2, -\mathbf{l}).
$$

Lemma 9. Suppose that $q = \pi \pi' r$ with $(p p', r) = 1$. Then one has

$$
W(\Delta, q; \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, p, p', v) = \left(\frac{p}{p'}\right) \left(\frac{p'}{p}\right) \theta(r; \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, v, \pi\pi', \pi\pi' pp'\Delta^{-1})
$$

$$
\times \mathcal{R}\left(\delta, p, \pi; \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, r\pi', \frac{rp'\pi'}{\delta'}, p'N\right)
$$

$$
\times \mathcal{R}\left(\delta', p', \pi'; \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, r\pi, \frac{rp\pi}{\delta}, pN\right).
$$

 \Box

Proof. Let

$$
a = \alpha \pi \pi' + b \pi' r + b' \pi r
$$

with $(\alpha, r) = (b, p) = (b', p') = 1$ and

$$
s = cp' + c'p
$$

with $(c, p) = (c', p') = 1$. Note that

$$
(app' + sq, app') = \Delta \iff (bp + c\pi, p\pi) = \delta \text{ and } (b'p' + c'\pi', p'\pi') = \delta'.
$$

Obviously

$$
\frac{app'+sq}{\Delta} = \alpha \frac{p\pi}{\delta} \frac{p'\pi'}{\delta'} + \frac{bp + c\pi}{\delta} \frac{p'\pi'}{\delta'} r + \frac{b'p' + c'\pi'}{\delta'} \frac{p\pi}{\delta} r.
$$

With the help of Lemma 1 (i), the desired result can be obtained by changing variables.

Lemma 10. *We have*

$$
\left| \mathcal{R} \left(\delta, p, \pi; \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, r \pi', \frac{rp'\pi'}{\delta'}, p'N \right) \mathcal{R} \left(\delta', p', \pi'; \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, r \pi, \frac{rp\pi}{\delta}, pN \right) \right|
$$

\$\leq \min\{\Delta^{-2} R^4 (4\pi \pi')^5 (1 + \Delta R^{-2})^{-1}, 2^6 R^4 (\pi \pi')^4\}.

Proof. We can assume that $\delta | p \pi$ and $\delta | p' \pi'$. Otherwise, the desired estimate holds trivially. We write

$$
\mathcal{R}(\delta, p, \pi) := \mathcal{R}\bigg(\delta, p, \pi; \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, r\pi', \frac{rp'\pi'}{\delta'}, p'N\bigg).
$$

Obviously $(1 + \delta R^{-1})^{-1} (1 + \delta' R^{-1})^{-1} \le (1 + \Delta R^{-2})^{-1}$. Thus it is enough to prove

$$
|\mathcal{R}(\delta, p, \pi)| \le \min\{\delta^{-2}R^2(2\pi)^5(1+\delta R^{-1})^{-1}, 8R^2\pi^4\}.
$$

Set $m_1 = r\pi'$ and $m_2 = rp'\pi'/\delta'$. It is clear that $p \nmid m_1m_2$.

When $\delta = 1$, $(bp + c\pi, \pi p) = \delta$ is equivalent to $\pi = 1$. So one has

$$
\mathcal{R}(1, p, \pi) = \sum_{c(p)^*} \left(\frac{c}{p}\right) e_p(-cp'N) S_d(p, cm_2^2, \mathbf{n})
$$

= $S(p, 1)^3 \sum_{c(p)^*} e_p(-cp'N) e_p\left(-4cm_2^2 \sum_{j=1}^3 n_j^2 \overline{d_j^2}\right).$

Then by Lemma 1 (iv) and Lemma 2, we get

$$
|\mathcal{R}(1, p, \pi)| \leq 2p^2.
$$

When $\delta = p$, we have $(bp + c\pi, \pi p) = \delta$ if and only if $p | \pi$ and $(b + c\frac{\pi}{n})$ $\frac{\pi}{p}, p) = 1.$ Hence

$$
\mathcal{R}(\delta, p, \pi) = \sum_{c(p)^*} \left(\frac{c}{p}\right) e_p(-cp'N) \sum_{\substack{b(\pi)^*\\(b+c\pi p^{-1}, \pi)=1}} e_{\pi}(\overline{bm_1}v)
$$

$$
\times S_d\left(\pi, \left(b+c\frac{\pi}{p}\right)m_2^2, \mathbf{n}\right) S_t(\pi, -bm_1^2, -\mathbf{l}).
$$

Using the trivial bound for summations over c and b , we get

$$
|\mathcal{R}(\delta, p, \pi)| \leq p\pi^4.
$$

 \Box

When $\delta = p^2$, we have $(bp + c\pi, \pi p) = \delta$ if and only if $\pi = p$ and $b + c \equiv 0 \pmod{p}$. Therefore, one has

$$
\mathcal{R}(\delta, p, \pi) = \sum_{c(p)^*} \left(\frac{c}{p}\right) e_p(-cp'N) \sum_{\substack{b(p)^* \\ b+c \equiv 0 \pmod{p}}} e_p(\overline{bm_1}v) S_{\mathbf{t}}(p, -bm_1^2, -\mathbf{l})
$$

$$
= \sum_{c(p)^*} \left(\frac{c}{p}\right) e_p(-cp'N) e_p(\overline{-cm_1}v) S_{\mathbf{t}}(p, cm_1^2, -\mathbf{l})
$$

$$
= S^3(p, 1) \sum_{c(p)^*} e_p(-cp'N) e_p(\overline{-cm_1}v) e_p\left(-\overline{4cm_1^2} \sum_{j=1}^3 l_j^2 \overline{t_j^2}\right).
$$

Then we get

$$
|\mathcal{R}(\delta, p, \pi)| \leq 2p^2.
$$

This completes the proof.

In view of Lemma 8, we define

$$
\xi(r, \eta, \mathbf{d}, \mathbf{t}) = \begin{cases} (r, \eta)(r, \mathbf{d})(r, \mathbf{t}) & \text{if } \eta \neq 0 \text{ and } (\mathbf{n}, \mathbf{l}) \neq \mathbf{0}, \\ r(r, \mathbf{d}^2)^{1/2} (r, \mathbf{t}^2)^{1/2} & \text{otherwise.} \end{cases}
$$

We summarize from Lemmas 8–10 that

Lemma 11. Suppose that $q = 2^u \pi \pi^r$ with $(2pp', r) = 1$. Then we have

$$
|W(\Delta, q; \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, p, p', v)|
$$

\$\leq 2^{4u+6}r^3\xi(r, \eta, \mathbf{d}, \mathbf{t}) \min\{\Delta^{-2}R^4(4\pi\pi')^5(1 + \Delta R^{-2})^{-1}, 2^6R^4(\pi\pi')^4\}\$.

The following estimate is a key ingredient in our proof.

Lemma 12. *Let* H > 0*. Define*

$$
\mathcal{U} = \sum_{|v| \leq P} \frac{1}{1+|v|} \sum_{\mathbf{d}} \sum_{\mathbf{t}} \sum_{\substack{(\mathbf{n}, \mathbf{l}) \neq \mathbf{0} \in \mathbb{Z}^6 \\ |n_j| \leq d_j H P^{\varepsilon}, |l_i| \leq t_i P^{\varepsilon} \\ \eta(\mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, v, b_1, b_2) = 0}} \max \left\{ \frac{|n_j|}{d_j H}, \frac{|l_i|}{t_i} \right\}^{-1}.
$$

Suppose that $(b_1b_2, 2d_1d_2d_3t_1t_2t_3) = 1$ *. Then we have*

$$
u \ll P^{\varepsilon}(D_1D_2D_3)^2(1+H).
$$

Remark. Recalling (4.2), when $b_1 = b_2 = 1$ and $v = 0$, one has the diagonal contributions from $\mathbf{d} = \mathbf{t}$ and $\mathbf{n} = \mathbf{l}$. Therefore in the case $b_1 = b_2 = 1$ and $H = 1$, we have the lower bound $\mathcal{U} \gg (D_1 D_2 D_3)^2$ which coincides with the upper bound (up to P^{ε}).

Proof. We decompose U to get

$$
\mathcal{U} \ll P^{\varepsilon} \sup_{\substack{N_j \le D_j H P^{\varepsilon} \\ L_i \le D_i P^{\varepsilon} \\ |v| \le P}} \mathcal{U}(N_1, N_2, N_3, L_1, L_2, L_3),
$$

where

$$
\mathcal{U}(N_1, N_2, N_3, L_1, L_2, L_3) = \sum_{\mathbf{d}} \sum_{\mathbf{t}} \sum_{\substack{n, l \\ N_j \le |n_j| \le 2N_j, L_i \le |l_i| \le 2L_i \\ (n,l) \neq 0 \in \mathbb{Z}^6 \\ \eta := \eta(\mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, v, b_1, b_2) = 0}} \max \left\{ \frac{|n_j|}{d_j H}, \frac{|l_i|}{t_i} \right\}^{-1}.
$$

Without loss of generality, we assume either $L_1 \neq 0$ or $N_1 \neq 0$.

We first consider the case $L_1 \neq 0$. Let

$$
e_i = \prod_{\substack{p \mid t_i \\ p \nmid d_1 d_2 d_3 t_1 t_2 t_3 t_i^{-1}}} p.
$$

Since e_i^2 is a divisor of $\eta - b_1^2 b_2^2 l_i^2 / (t_i^2 b_1^2)$ lcm and $(b_1^2 b_2^2 t_i^{-2}$ lcm, $e_i^2) = 1$, we have $e_i^2 | l_i^2$ and then $e_i | l_i$. Hence for fixed **d** and **t**, there are at most $2L_1e_1^{-1}(1 + 2L_2e_2^{-1})(1 + 2L_3e_3^{-1})$ possible choices for l. Clearly

$$
\max\left\{\frac{|n_j|}{d_jH}, \frac{|l_i|}{t_i}\right\}^{-1} \le t_1 L_1^{-1}.
$$

Now fix **d**, **t** and **l**, we claim there are at most $O(P^{\epsilon} + HP^{\epsilon})$ possible choices for n_1 . Suppose that (n_1, n_2, n_3) and (n'_1, n'_2, n'_3) are two solutions for $\eta(\mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, v, b_1, b_2) = 0$. Then

$$
\sum_{j=1}^{3} \frac{n_j^2 - n_j'^2}{d_j^2} = 0.
$$

We write it in the form

$$
\frac{[d_1, d_2, d_3]^2}{d_1^2} (n_1^2 - n_1^2) = -\frac{[d_1, d_2, d_3]^2}{d_2^2} (n_2^2 - n_2^2) - \frac{[d_1, d_2, d_3]^2}{d_3^2} (n_3^2 - n_3^2).
$$

Let

$$
k = \prod_{\substack{p \mid d_1 \\ p \nmid d_2 d_3}} p.
$$

We see that $n_1^2 \equiv n_1'^2 \pmod{k^2}$. So we can find $K \mid k^2$ with $K \ge k$ such that either $K \mid n_1 + n'_1$ 1 or $K | n_1 - n_1$ \int_1^1 . We deal with $K | n_1 - n'_1$ $\frac{1}{1}$, and the other case can be handled similarly. Suppose that $n_1 - n'_1 = Km$ for some m with $0 \le |m| \le d_1 H P^{\varepsilon} K^{-1}$. Note that $K \ge d_1 P^{-\varepsilon}$ due to $K \ge k$ and the condition (2.8). Then the number of possible choices for m is $O((1 + H)P^{\varepsilon})$. The number of K satisfying $K \mid k^2$ is at most $O(P^{\varepsilon})$. Thus there are at most $O((1 + H)P^{\varepsilon})$ choices for n_1 . Then n_2, n_3 can be determined (up to at most P^{ε} choices) by **d**, **t**, **l**, n_1 due to the equation $\eta = 0$. Hence

$$
\mathcal{U}(N_1, N_2, N_3, L_1, L_2, L_3) \ll \sum_{\mathbf{d}} \sum_{\mathbf{t}} \frac{L_1}{e_1} \left(1 + \frac{L_2}{e_2} \right) \left(1 + \frac{L_3}{e_3} \right) \frac{t_1}{L_1} (1 + H) P^{\varepsilon}
$$

$$
\ll \sum_{\mathbf{d}} \sum_{\mathbf{t}} \prod_{i=1}^3 \frac{t_i}{e_i} (1 + H) P^{\varepsilon}.
$$

Note that

$$
t_i \leq e_i \prod_{j=1}^3 (d_j, t_i)(t_1, t_2)(t_1, t_3)(t_2, t_3) \ll e_i \prod_{j=1}^3 (d_j, t_i) P^{\varepsilon},
$$

so

$$
\mathcal{U}(N_1, N_2, N_3, L_1, L_2, L_3) \ll \sum_{\mathbf{d}} \sum_{t} \prod_{i=1}^3 \prod_{j=1}^3 (d_j, t_i)(1 + H) P^{\varepsilon}
$$

$$
\ll (D_1 D_2 D_3)^2 (1 + H) P^{\varepsilon}.
$$

Now we assume $N_1 \neq 0$ and $\mathbf{l} = \mathbf{0}$. Let

$$
h = \prod_{\substack{p \mid d_1 \\ p \nmid d_2 d_3 t_1 t_2 t_3}} p.
$$

The similar argument as before implies $h | n_1$. So there are at most $4N_1h^{-1}$ choices for n_1 . Then n_2 , n_3 will be determined. We arrive at

$$
\mathcal{U}(N_1, N_2, N_3, L_1, L_2, L_3) \ll \sum_{\mathbf{d}} \sum_{\mathbf{t}} (N_1 h^{-1}) d_1 H N_1^{-1}
$$

$$
\ll \sum_{\mathbf{d}} \sum_{\mathbf{t}} \prod_i (d_1, t_i) H P^{\varepsilon}
$$

$$
\ll (D_1 D_2 D_3)^2 H P^{\varepsilon}.
$$

The proof is completed.

To handle the contribution from $\eta \neq 0$, we need the following.

Lemma 13. *Let*

$$
\mathcal{V} = \sum_{|v| \le P} \frac{1}{1+|v|} \sum_{\mathbf{d}, \mathbf{t}} \sum_{r \le P} \frac{1}{r} \sum_{\substack{(\mathbf{n}, \mathbf{l}) \ne \mathbf{0} \in \mathbb{Z}^6 \\ |n_j| \le d_j H P^{\varepsilon}, |l_i| \le t_i P^{\varepsilon} \\ (d_j^2, r) | n_j, (t_i^2, r) | l_i \\ \eta := \eta(\mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, v, b_1, b_2) \ne 0}} (r, \eta)(r, \mathbf{d})(r, \mathbf{t}) \max \left\{ \frac{n_j^2}{d_j^2 H^2}, \frac{l_i^2}{t_i^2} \right\}^{-1}
$$

with $H > 0$ *. One has*

$$
\mathcal{V}\ll P^{\varepsilon}(D_1D_2D_3)^4(1+H)^3.
$$

Proof. By changing variables, we get

$$
\mathcal{V} \leq \sum_{|v| \leq P} \frac{1}{1+|v|} \sum_{\substack{\mathbf{d}, \mathbf{t} \\ k_i | t_i}} \sum_{\substack{|h_1, h_2, h_3, h_4 \geq k_3 \\ |h_j| \leq d_j H P^{\varepsilon}}} \sum_{\substack{(\mathbf{n}, \mathbf{l}) \neq \mathbf{0} \in \mathbb{Z}^6 \\ |h_j| \leq d_j H P^{\varepsilon}}} \max \left\{ \frac{n_j^2}{d_j^2 H^2}, \frac{l_i^2}{t_i^2} \right\}^{-1} \sum_{\substack{r \leq P \\ r \leq P}} \frac{(r, \eta)}{r}
$$
\n
$$
\ll \sum_{\substack{\mathbf{d}, \mathbf{t} \\ \mathbf{d}, \mathbf{t} \\ h_j | d_j}} \sum_{\substack{k_i | t_i \\ k_i | t_i}} \sum_{\substack{|h_1, h_2, h_3, h_4 \geq k_3 \\ |h_j| \leq d_j H P^{\varepsilon}}} \sum_{\substack{(\mathbf{n}, \mathbf{l}) \neq \mathbf{0} \in \mathbb{Z}^6 \\ |h_j| \leq d_j H P^{\varepsilon}}} \max \left\{ \frac{n_j^2}{d_j^2 H^2}, \frac{l_i^2}{t_i^2} \right\}^{-1} P^{\varepsilon}.
$$

 \Box

Without loss of generality, we assume

$$
\max\left\{\frac{n_j^2}{d_j^2H^2}, \frac{l_i^2}{t_i^2}\right\} = \frac{n_1^2}{d_1^2H^2}.
$$

First we handle the case that $(n_2, n_3, l_1, l_2, l_3) \in \mathbb{Z}^5$ is non-zero. We have

$$
\sum_{h_j \, | \, n_j} 1 \le 1 + (|n_1|d_1^{-1}H^{-1})d_j H h_j^{-1} \quad \text{for } 2 \le j \le 3
$$

and

$$
\sum_{k_i \,|\, l_i} 1 \le 1 + (|n_1|d_1^{-1}H^{-1})t_i k_i^{-1} \quad \text{for } 1 \le i \le 3.
$$

Since $(n_2, n_3, l_1, l_2, l_3) \in \mathbb{Z}^5$ is non-zero, at least one of the five inequalities above holds with 1 omitted. Hence

$$
\mathcal{V} \ll \sum_{\mathbf{d}, \mathbf{t}} \sum_{h_j \mid d_j} \sum_{k_i \mid t_i} h_1 h_2 h_3 k_1 k_2 k_3 \sum_{\substack{h_1 \mid n_1 \\ 0 < |n_1| \le d_1 H P^\varepsilon}} \frac{d_1^2 H^2 P^\varepsilon}{n_1^2} \Biggl(\Biggl(1 + \frac{|n_1| d_2}{d_1 h_2} \Biggr) \Biggl(1 + \frac{|n_1| d_3}{d_1 h_3} \Biggr)
$$
\n
$$
\times \left(1 + \frac{|n_1| t_1}{d_1 H k_1} \right) \Biggl(1 + \frac{|n_1| t_2}{d_1 H k_2} \Biggr) \Biggl(1 + \frac{|n_1| t_3}{d_1 H k_3} \Biggr) - 1 \Biggr).
$$

A simple calculation reveals that

$$
\mathcal{V} \ll P^{\varepsilon} (D_1 D_2 D_3)^4 (1+H)^3.
$$

Now we turn to the case $n_2 = n_3 = l_1 = l_2 = l_3 = 0$. Note that η is independent of d_2 , d_3 and t in this case. Switching the summations, we arrive at

$$
\mathcal{V} \ll \sum_{|v| \leq P} \frac{1}{1+|v|} \sum_{d_1} \sum_{r \leq P} \frac{1}{r} \sum_{\substack{0 < |n_1| \leq d_1 H P^\varepsilon \\ (r, d_1) | n_1}} \frac{d_1^2 H^2(r, \eta)(r, d_1)}{n_1^2} \sum_{\substack{d_2, d_3, t \\ d_2, d_3, t}} (r, d_2)(r, d_3)(r, t)
$$
\n
$$
\ll \sum_{|v| \leq P} \frac{1}{1+|v|} \sum_{d_1} \sum_{r \leq P} \frac{1}{r} \sum_{\substack{0 < |n_1| \leq d_1 H P^\varepsilon \\ n \neq 0}} d_1^2 H^2(r, \eta) n_1^{-1} D_1 (D_2 D_3)^2 P^\varepsilon.
$$

Hence we easily obtain $V \ll D_1^4 D_2^2 D_3^2 H^2 P^{\varepsilon}$. The proof is thus completed.

For $H > 0$, we define

$$
\mathcal{N}_{\mathbf{d},q}(H) = \{ \mathbf{n} \in \mathbb{Z}^3 : |n_i| \le d_i H P^{\varepsilon}, n_i \equiv 0 \pmod{(q, d_i^2)}, i = 1, 2, 3 \},\
$$

and write $\mathcal{N}_{\mathbf{d},q} = \mathcal{N}_{\mathbf{d},q}(1)$. Let

$$
\mathcal{Y}_1 = \sum_{|v| \leq P} \frac{1}{1+|v|} \sum_{\mathbf{d}, \mathbf{t}} \sum_{\substack{\Delta \mid (pp')^2}} \sum_{q \leq P} \frac{\Delta^3}{q^6}
$$

$$
\times \sum_{\mathbf{n} \in \mathcal{N}_{q, \mathbf{d}}(pp'/\Delta)} |W(\Delta, q; \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, p, p', v)| \mathcal{C}(q, \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, pp'\Delta^{-1}),
$$

 \Box

where

(4.6)
$$
\mathcal{C}(q, \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, H) = \begin{cases} \min & \text{if } (\mathbf{n}, \mathbf{l}) \neq \mathbf{0}, \\ q^2 P^{-2} & \text{if } (\mathbf{n}, \mathbf{l}) = \mathbf{0}, \end{cases}
$$

and

$$
\min = \min \left\{ \frac{q^2}{P^2} \left(\sum_{j=1}^3 \left(\frac{n_j^2}{d_j^2 H^2} + \frac{l_i^2}{t_i^2} \right) \right)^{-1}, \frac{q}{P} \left(\sum_{j=1}^3 \left(\frac{|n_j|}{d_j H} + \frac{|l_i|}{t_i} \right) \right)^{-1} \right\}.
$$

Let

$$
\mathcal{Y}_2 = \sum_{|v| \le P} \frac{1}{1+|v|} \sum_{\mathbf{d}} \sum_{\mathbf{t}} \sum_{q \le P} \frac{1}{q^6} \sum_{\substack{(\mathbf{n}, \mathbf{l}) \ne \mathbf{0} \in \mathbb{Z}^6 \\ \mathbf{n} \in \mathcal{N}_{q,\mathbf{t}} \\ |\mathbf{t} \in \mathcal{N}_{q,\mathbf{t}}}} |\theta(q; \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, v, 1, 1)|
$$

$$
\times \min \left\{ \frac{q^2}{P^2} \left(\sum_{j=1}^3 \left(\frac{n_j^2}{d_j^2} + \frac{l_i^2}{t_i^2} \right) \right)^{-1}, \frac{q}{P} \left(\sum_{j=1}^3 \left(\frac{|n_j|}{d_j} + \frac{|l_i|}{t_i} \right) \right)^{-1} \right\}
$$

With the help of Lemmas 8–13, we establish the following result.

Lemma 14. Let \mathcal{Y}_1 and \mathcal{Y}_2 be defined as above. Then one has

$$
\mathcal{Y}_1 \ll (D_1 D_2 D_3)^2 P^{\varepsilon - 1} R^6 + (D_1 D_2 D_3)^4 P^{-2 + \varepsilon} R^{10},
$$

$$
\mathcal{Y}_2 \ll (D_1 D_2 D_3)^2 P^{-1 + \varepsilon} + (D_1 D_2 D_3)^4 P^{-2 + \varepsilon}.
$$

Proof. The proofs for \mathcal{Y}_1 and \mathcal{Y}_2 are similar. Indeed, the argument for \mathcal{Y}_2 is easier, because there is no R involved. We only work out the details for \mathcal{Y}_1 .

We write $y_1 = y_1^{(1)} + y_1^{(2)} + y_1^{(3)}$ $y_1^{(3)}$, where $y_1^{(1)}$ $j_1^{(1)}$ is the contribution from $(n, l) = 0$, $\mathcal{Y}_1^{(2)}$ $\int_{1}^{(2)}$ is the contribution from those terms with $(\mathbf{n}, \mathbf{l}) \neq \mathbf{0}$ but $\eta := \eta(\mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, v, \pi \pi', \pi \pi' pp'/\Delta) = 0$, and $y_1^{(3)}$ $\binom{3}{1}$ is the contribution from the remaining terms. By Lemma 11, when $(\mathbf{n}, \mathbf{l}) = \mathbf{0}$ or $\eta = 0$,

(4.7)
$$
W(\Delta, q; \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, p, p', v) \ll 2^{4u} r^4 (r, \mathbf{d}^2)^{1/2} (r, \mathbf{t}^2)^{1/2} \Delta^{-2} R^4 (\pi \pi')^5 (1 + \Delta R^{-2})^{-1},
$$

where we have used the decomposition $q = 2^u \pi \pi^r$ with $(2pp', r) = 1$. On applying the estimate (4.7), we get

$$
\mathcal{Y}_1^{(1)} \ll P^{-2} R^4 \sum_{|v| \leq P} \frac{1}{1+|v|} \sum_{\mathbf{d}, \mathbf{t}} \sum_{\Delta \, | \, (pp')^2} \sum_{2^{\mathcal{U}} \pi \pi' r \leq P} \frac{\Delta \pi \pi' (r, \mathbf{d}^2)^{1/2} (r, \mathbf{t}^2)^{1/2}}{1+\Delta R^{-2}}.
$$

Recalling the condition (2.8), we obtain

$$
\sum_{r \leq \frac{P}{2^{u} \pi \pi'}} (r, \mathbf{d}^{2})^{1/2} (r, \mathbf{t}^{2})^{1/2} \leq \left(\sum_{r \leq \frac{P}{2^{u} \pi \pi'}} (r, \mathbf{d}^{2})\right)^{1/2} \left(\sum_{r \leq \frac{P}{2^{u} \pi \pi'}} (r, \mathbf{t}^{2})\right)^{1/2}
$$

\$\ll P^{\varepsilon} \left(\sum_{r \leq \frac{P}{2^{u} \pi \pi'}} (r, d_{1}^{2} d_{2}^{2} d_{3}^{2})\right)^{1/2} \left(\sum_{r \leq \frac{P}{2^{u} \pi \pi'}} (r, t_{1}^{2} t_{2}^{2} t_{3}^{2})\right)^{1/2}\$
\$\ll P^{\varepsilon+ \varepsilon}\$
\$\ll P^{\varepsilon+ \varepsilon}\$

:

Then one can get

$$
\sum_{2^u \pi \pi' r \le P} \pi \pi'(r, \mathbf{d}^2)^{1/2} (r, \mathbf{t}^2)^{1/2} \ll P^{1+\varepsilon}.
$$

It is easy to see

$$
\sum_{\Delta \,|\, (pp')^2} \frac{\Delta}{1 + \Delta R^{-2}} \ll R^2.
$$

We can now conclude that

$$
y_1^{(1)} \ll (D_1 D_2 D_3)^2 P^{\varepsilon - 1} R^6.
$$

.1/

Combining (4.7) and

$$
\mathcal{C}\left(q,\mathbf{d},\mathbf{t},\mathbf{n},\mathbf{l},\frac{pp'}{\Delta}\right)\ll \frac{q}{P}\max\left\{\frac{|n_j|}{d_j\,pp'/\Delta},\frac{|l_i|}{t_i}\right\}^{-1},\,
$$

one can deduce that

$$
y_1^{(2)} \ll P^{-1} R^4 \sum_{|v| \le P} \frac{1}{1+|v|} \sum_{\mathbf{d}, \mathbf{t}} \sum_{\Delta \mid (pp')^2} \sum_{\substack{2^u \pi \pi' r \le P \\ |n_j| \le d_j P^{\epsilon} pp'/\Delta \\ |l_i| \le t_i P^{\epsilon} \\ n=0}} \frac{\Delta}{2^u r (1+\Delta R^{-2})}
$$

$$
\times (r, \mathbf{d}^2)^{1/2} (r, \mathbf{t}^2)^{1/2} \max \left\{ \frac{|n_j|}{d_j pp'/\Delta}, \frac{|l_i|}{t_i} \right\}^{-1}.
$$

Note that

$$
\sum_{2^u \pi \pi' r \le P} \frac{1}{2^u r} (r, \mathbf{d}^2)^{1/2} (r, \mathbf{t}^2)^{1/2} \ll P^{\varepsilon},
$$

we have

$$
y_1^{(2)} \ll P^{-1+\varepsilon} R^4 \sum_{\Delta \mid (pp')^2} \frac{\Delta}{1 + \Delta R^{-2}} \sum_{|v| \le P} \frac{1}{1 + |v|}
$$

$$
\times \sum_{\substack{\mathbf{d}, \mathbf{t} \\ |n_j| \le d_j P^\varepsilon p p' / \Delta}} \max \left\{ \frac{|n_j|}{d_j p p' / \Delta}, \frac{|l_i|}{t_i} \right\}^{-1}.
$$

Then one can conclude, by appealing to Lemma 12, that

$$
y_1^{(2)} \ll P^{-1+\varepsilon} R^4 \sum_{\Delta \, | \, (pp')^2} \frac{\Delta}{1 + \Delta R^{-2}} (D_1 D_2 D_3)^2 \left(1 + \frac{p p'}{\Delta} \right)
$$

$$
\ll (D_1 D_2 D_3)^2 P^{\varepsilon - 1} R^6.
$$

For $y_1^{(3)}$ we shall apply

$$
W(\Delta, q; \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, p, p', v) \ll 2^{4u} r^3(r, \eta)(r, \mathbf{d})(r, \mathbf{t}) R^4(\pi \pi')^4
$$

by Lemma 11. Note that $\mathcal{N}_{q,\mathbf{d}}(pp'/\Delta) = \mathcal{N}_{r,\mathbf{d}}(pp'/\Delta)$ for $q = 2^u \pi \pi^r r$, and

$$
\mathcal{C}\left(q,\mathbf{d},\mathbf{t},\mathbf{n},\mathbf{l},\frac{pp'}{\Delta}\right) \ll \frac{q^2}{P^2} \max\left\{\frac{n_j^2}{d_j^2 (pp'/\Delta)^2},\frac{l_i^2}{t_i^2}\right\}^{-1}.
$$

Thus, one has

$$
y_1^{(3)} \ll P^{-2} R^4 \sum_{\Delta \mid (pp')^2} \Delta \sum_{|v| \le P} \frac{1}{1+|v|} \sum_{2^u \pi \pi' r \le P} \frac{1}{r}
$$

$$
\times \sum_{\substack{\mathbf{d}, \mathbf{t} \\ \mathbf{d}, \mathbf{t} \in \mathcal{N}_{r,\mathbf{d}}(\Delta/(pp')) \\ \mathbf{d} \in \mathcal{N}_{r,\mathbf{t}}} (r, \eta)(r, \mathbf{d})(r, \mathbf{t}) \max \left\{ \frac{n_j^2}{d_j^2 (pp'/\Delta)^2}, \frac{l_i^2}{t_i^2} \right\}^{-1}.
$$

By Lemma 13, we have

$$
\mathcal{Y}_1^{(3)} \ll P^{-2+\varepsilon} R^4 \sum_{\Delta \, | \, (pp')^2} \Delta(D_1 D_2 D_3)^4 \bigg(1 + \frac{pp'}{\Delta}\bigg)^3 \ll (D_1 D_2 D_3)^4 P^{\varepsilon - 2} R^{10}.
$$

The assertion is established.

Lemma 15. *Let*

$$
\mathcal{F} = \sum_{0 < |l| \le R^2 Q^2 P^{\varepsilon - 2}} \left(\frac{l}{p p'} \right)
$$
\n
$$
\times \sum_{\substack{q_1, q_2 \\ (q_1 q_2, p p') = 1}} \left(q_1 q_2 \right)^{-3} \left(\frac{q_1 q_2}{p p'} \right) e_{p p'} \left(-\overline{q_1 q_2} l N \right) e \left(\frac{l n}{q_1 q_2 p p'} \right)
$$
\n
$$
\times \sum_{\substack{q_1, q_2 \\ \pi_1(q_1)^* \pi_2(q_2)^* \\ p p'(a_1 q_2 + a_2 q_1) \equiv l \pmod{q_1 q_2}}} S_{\mathbf{d}}(q_1, -a_1) S_{\mathbf{t}}(q_2, -a_2).
$$

Then we have

$$
\mathcal{F} \ll P^{-4+\varepsilon} Q^3 R^2 + P^{-4+\varepsilon} Q^{14/5} R^{24/5}.
$$

Proof. We modify the argument of Heath-Brown and Tolev [9]. Let

$$
q_j = g_j b_j, \quad 1 \le j \le 2,
$$

where

$$
g_1 = \prod_{\substack{p^k \parallel q_1 \\ p \nmid 2d_1d_2d_3(q_1, q_2)}} p^k \quad \text{and} \quad g_2 = \prod_{\substack{p^k \parallel q_2 \\ p \nmid 2d_1d_2d_3(q_1, q_2)}} p^k.
$$

Then

$$
(g_1, g_2) = (g_1g_2, b_1b_2) = (g_1, 2d_1d_2d_3) = (g_2, 2t_1t_2t_3) = 1.
$$

Let $a_j = \alpha_j b_j + \beta_j g_j$ for $j = 1, 2$. Then

$$
pp'(a_1q_2 + a_2q_1) \equiv l \pmod{q_1q_2}
$$

is equivalent to the three conditions

$$
pp'\alpha_1b_1b_2g_2 \equiv l \pmod{g_1},
$$

$$
pp'\alpha_2b_1b_2g_1 \equiv l \pmod{g_2},
$$

$$
pp'g_1g_2(\beta_1b_2+\beta_2b_1) \equiv l \pmod{b_1b_2}.
$$

 \Box

Hence by Lemma 1 (i), the inner multiple sum over a_1, a_2 in $\mathcal F$ is equal to

$$
\left(\frac{-pp'b_1b_2g_2l}{g_1}\right)\left(\frac{-pp'b_1b_2g_1l}{g_2}\right)S^3(g_1,1)S^3(g_2,1)\Xi,
$$

where

$$
\Xi = \Xi(pp'g_1g_2) = \sum_{\substack{\beta_1(b_1)^*, \beta_2(b_2)^*\\p p' g_1 g_2(\beta_1 b_2 + \beta_2 b_1) = l \pmod{b_1 b_2}}} S_{\mathbf{d}}(b_1, -\beta_1) S_{\mathbf{t}}(b_2, -\beta_2).
$$

Let $b_j = B_j \Delta$ for $j = 1, 2$ with $\Delta = (b_1, b_2)$. Then $\Xi = 0$ if $\Delta \nmid l$, and for $l = \Delta v$ we have

$$
\Xi(pp'g_1g_2) = \sum_{\substack{\beta_1(B_1\Delta)^*, \beta_2(B_2\Delta)^*\\p p' g_1 g_2(\beta_1 B_2 + \beta_2 B_1) \equiv v \pmod{B_1 B_2\Delta}}} S_{\mathbf{d}}(B_1\Delta, \beta_1) S_{\mathbf{t}}(B_2\Delta, \beta_2).
$$

In order to change variables, we introduce the conditions

(4.8)
\n
$$
\begin{cases}\n(g_1, g_2) = (g_1 g_2, B_1 B_2 \Delta) = (B_1, B_2) = 1, \\
(g_1, 2d_1 d_2 d_3) = (g_2, 2t_1 t_2 t_3) = 1, \\
\rho_{\mathbf{d}}(B_1 \Delta) = \rho_{\mathbf{d}}(\Delta), \quad \rho_{\mathbf{t}}(B_2 \Delta) = \rho_{\mathbf{t}}(\Delta), \\
(B_1 B_2 \Delta g_1 g_2, pp') = 1, \quad |v|(pp')^{-1} P^{2-\varepsilon} < B_1 B_2 \Delta g_1 g_2,\n\end{cases}
$$

where for $\mathbf{k} = (k_1, k_2, k_3)$ we use the notation

$$
\rho_{\mathbf{k}}(m) = \prod_{\substack{p \mid m \\ p+2k_1k_2k_3}} p.
$$

By changing variables we arrive at

$$
\mathcal{F} = \sum_{\substack{v,\Delta\\0 < |v\Delta| \le R^2 Q^2 P^{\varepsilon - 2}}} \left(\frac{v\Delta}{pp'}\right) \sum_{B_1, B_2} (B_1 B_2)^{-3} \Delta^{-6} \left(\frac{B_1 B_2}{pp'}\right) \\
\times \sum_{\substack{g_1, g_2\\(4,8)}} (g_1 g_2)^{-3} \left(\frac{g_1 g_2}{pp'}\right) e_{pp'} (-\overline{g_1 g_2 B_1 B_2 \Delta v N}) e \left(\frac{vn}{g_1 g_2 B_1 B_2 \Delta pp'}\right) \\
\times \left(\frac{-pp' B_1 B_2 g_2 \Delta v}{g_1}\right) \left(\frac{-pp' B_1 B_2 g_1 \Delta v}{g_2}\right) S^3(g_1, 1) S^3(g_2, 1) \Xi(pp' g_1 g_2).
$$

Let

$$
\xi(g_1, g_2) = e\left(\frac{vn}{g_1g_2B_1B_2\Delta pp'}\right)\left(\frac{g_1g_2}{pp'}\right)\left(\frac{-pp'g_2}{g_1}\right)\left(\frac{-pp'g_1}{g_2}\right)\frac{S^3(g_1, 1)S^3(g_2, 1)}{g_1^3g_2^3}.
$$

Note that $\Xi(\lambda)$ depends on λ (mod $B_1B_2\Delta$) only. Hence

$$
\mathcal{F} = \sum_{\substack{v,\Delta\\(v\Delta, pp')=1\\0<|v\Delta|\leq R^2Q^2P^{\varepsilon-2}}} \left(\frac{v}{pp'}\right) \sum_{B_1,B_2} (B_1B_2)^{-3} \Delta^{-6} \sum_{\lambda \pmod{8B_1B_2\Delta}} \Xi(\lambda) \left(\frac{B_1B_2\Delta}{\lambda}\right)
$$

$$
\times \sum_{\substack{g_1,g_2\\(4.8)\\p p'g_1g_2 \equiv \lambda \pmod{8B_1B_2\Delta}}} e_{pp'}(-\overline{g_1g_2B_1B_2\Delta}vN) \left(\frac{v}{g_1}\right) \left(\frac{v}{g_2}\right) \xi(g_1,g_2).
$$

Moreover, in view of (4.8) and the condition

$$
pp'g_1g_2 \equiv \lambda \pmod{8B_1B_2\Delta},
$$

the summation $\sum_{\lambda \pmod{8B_1B_2\Delta}}$ can be replaced by $\sum_{\lambda \pmod{8B_1B_2\Delta}}$. From Lemma 1 (ii), (iii), (iv), and (2.8),

$$
\Xi(\lambda) \ll \Delta^4 (B_1 B_2)^{3/2} (\Delta B_1, \mathbf{d}^2)^{1/2} (\Delta B_2, \mathbf{t}^2)^{1/2} \ll \Delta^5 (B_1 B_2)^2 P^{\varepsilon}.
$$

By the dyadic argument, we have

(4.9)
$$
\mathcal{F} \ll \log^2 P \sup_{\substack{G_1 \leq G_1' \leq 2G_1 \\ G_2 \leq G_2' \leq 2G_2}} \mathcal{F}(G_1, G_2),
$$

where

$$
\mathcal{F}(G_1, G_2) = \sum_{\substack{v, \Delta \\ (v\Delta, pp')=1}} \sum_{B_1, B_2} (B_1 B_2)^{-1} \Delta^{-1} \sum_{\lambda \pmod{8B_1B_2\Delta}^*} (\Delta_{1}B_2 \Delta)^* \times |\sum_{\substack{G_1 \le g_1 \le G_1', G_2 \le g_2 \le G_2' \\ (4.8) \\ pp'g_1g_2 \equiv \lambda \pmod{8B_1B_2\Delta}}} e_{pp'}(-\overline{g_1g_2B_1B_2\Delta}vN) \left(\frac{v}{g_1}\right) \left(\frac{v}{g_2}\right) \xi(g_1, g_2)|.
$$

Without loss of generality, we assume $G_1 \leq G_2$. In view of (4.8), the multiple summations over B_1 , B_2 are naturally restricted by

(4.10)
$$
\begin{cases} \rho_{\mathbf{d}}(B_1 \Delta) = \rho_{\mathbf{d}}(\Delta), & \rho_{\mathbf{t}}(B_2 \Delta) = \rho_{\mathbf{t}}(\Delta), \\ (B_1 B_2, p p') = 1, \\ |v| R^{-2} p^{2-\varepsilon} \le 16 B_1 B_2 \Delta G_1 G_2. \end{cases}
$$

In view of the congruence condition $pp'g_1g_2 \equiv \lambda \pmod{8B_1B_2\Delta}$, for fixed p, p', λ and g_1 , we have

$$
\xi(g_1, g_2) = e \left(\frac{v n}{g_1 g_2 B_1 B_2 \Delta p p'} \right) g_1^{-3/2} g_2^{-3/2} \epsilon,
$$

where $|\epsilon| = 1$ and ϵ is independent of g_2 . Partial summation gives

$$
\mathcal{F}(G_1, G_2) \ll \sup_{\substack{G_2 \leq G, G' \leq G'_2 \\ G_1 \leq g_1 \leq G'_1}} G_1^{-1/2} G_2^{-3/2} P^{\varepsilon} \sum_{\substack{v, \Delta \\ (v \Delta, pp') = 1 \\ 0 < |v\Delta| \leq R^2 Q^2}} \Delta^{-1} \sum_{\substack{B_1, B_2 \\ (4.10) \\ (4.10) \\ A \pmod{8B_1 B_2 \Delta}}}^{R_1 \leq G_1} (B_1 B_2)^{-1}
$$
\n
$$
\times \sum_{\substack{\lambda \pmod{8B_1 B_2 \Delta}}} \sum_{\substack{B_1 \geq g \geq G' \\ (4.11) \\ G \leq g_2 \leq G' \\ (4.11) \\ pp' g_1 g_2 \equiv \lambda \pmod{8B_1 B_2 \Delta}}^{R_1 \geq R^2 Q^2 P^{\varepsilon - 2}}
$$

where the condition (4.11) comprises

(4.11)
$$
\begin{cases} (g_1, g_2) = (g_2, B_1 B_2 \Delta) = 1, \\ (g_2, 2t_1 t_2 t_3) = 1, \\ (g_2, pp') = 1, \quad |v|(pp')^{-1} p^{2-\varepsilon} < B_1 B_2 \Delta g_1 g_2. \end{cases}
$$

As in [9], we use two different estimates according to $G_2 \geq H$ or otherwise, where H will be chosen later. The summation over g_2 is of the type

(4.12)
$$
\mathcal{M} = \sum_{\substack{K \leq g \leq K' \\ (g,u)=1 \\ g \equiv \lambda' \pmod{8B_1B_2\Delta}}} e_{pp'}(\overline{gm_1}m_2) \left(\frac{v}{g}\right),
$$

where $G \leq K$, $K' \leq G'$ and $(m_1m_2, pp') = (2B_1B_2\Delta, \lambda') = 1$. We shall prove

(4.13)
$$
\mathcal{M} \ll P^{\varepsilon} G_2 (B_1 B_2 \Delta p p')^{-1} + |v| R^2 P^{\varepsilon}.
$$

With (4.13), we can get

$$
\mathcal{F}(G_1, G_2) \ll G_1^{-1/2} G_2^{-3/2} P^{\varepsilon} \sum_{\substack{v,\Delta\\0<|v\Delta|\leq R^2Q^2P^{\varepsilon-2}}}\sum_{\substack{(\mathbf{d},\mathbf{d},\mathbf{d})\\(\mathbf{d},\mathbf{d})}} (G_2(B_1B_2\Delta pp')^{-1} + |v|R^2)
$$

\$\ll G_1^{-1/2} G_2^{-3/2} P^{\varepsilon} \sum_{\substack{v,\Delta\\0<|v\Delta|\leq R^2Q^2P^{\varepsilon-2}}}\frac{|v|^{\alpha-2}G_1G_2^2 + |v|R^2}{(|v|^{-1}P^{-2}G_1G_2^2 + |v|R^2)} \sum_{\substack{B_1,B_2\\(\mathbf{d},\mathbf{10})}} 1.

Note that

(4.14)
$$
\sum_{\substack{B_1, B_2 \ (4.10)}} 1 \leq \sum_{\substack{B_1 \leq P \ p \, | \, B_1 \Rightarrow p \, | \, 2d_1d_2d_3\Delta}} \sum_{\substack{B_2 \leq P \ p \, | \, 2t_1t_2t_3\Delta}} 1 \ll P^{\varepsilon}.
$$

We now conclude

$$
\mathcal{F}(G_1, G_2) \ll P^{-4+\varepsilon} R^2 Q^2 G_1^{1/2} G_2^{1/2} + G_1^{-1/2} G_2^{-3/2} R^6 Q^4 P^{-4+\varepsilon}
$$

$$
\ll P^{-4+\varepsilon} R^2 Q^3 + R^6 Q^4 P^{-4+\varepsilon} H^{-3/2}.
$$

To prove (4.13), we first remove the restriction $(g, u) = 1$, getting

$$
\mathcal{M} = \sum_{w|u} \mu(w) \left(\frac{v}{w}\right) \sum_{\substack{Kw^{-1} \le g \le K'w^{-1} \\ g \equiv \lambda' \pmod{8B_1B_2\Delta}}} e_{pp'}(\overline{g w m_1} m_2) \left(\frac{v}{g}\right).
$$

We divide the inner summation into $O(G_2w^{-1}(8B_1B_2\Delta pp'|v|)^{-1})$ complete sums and at most one incomplete sum

(4.15)
$$
\mathcal{M} \ll \sum_{w \, | \, u} (G_2 w^{-1} (8B_1 B_2 \Delta p p' |v|)^{-1} |\mathcal{M}_0| + O(|v|R^2)),
$$

where

$$
\mathcal{M}_0 = \sum_{\substack{g \pmod{8B_1B_2\Delta pp'|v|}\\ gw \equiv \lambda' \pmod{8B_1B_2\Delta}}} e_{pp'}(\overline{gwm_1}m_2) \left(\frac{v}{g}\right)
$$

and the error $O(|v|R^2)$ is the contribution from the incomplete sum. Recalling the condition $(B_1 B_2 \Delta v, pp') = 1$, we change variables, by $g = s8B_1B_2\Delta|v| + kpp'$, to deduce that

$$
\mathcal{M}_0 = \sum_{\substack{k \pmod{8B_1B_2\Delta|v|} \\ kpp'w \equiv \lambda' \pmod{8B_1B_2\Delta}}} \left(\frac{v}{kpp'}\right) \sum_{s \pmod{pp'}^*} e_{pp'}(\overline{s8B_1B_2\Delta|v|wm_1m_2}).
$$

The inner sum is a Ramanujan sum, so $\mathcal{M}_0 \ll |v|$. Now (4.13) follows from (4.15).

When $G_2 < H$, we apply the trivial bound to get

$$
\mathcal{F}(G_1, G_2) \ll \sup_{G, G'} G_1^{-1/2} G_2^{-3/2} \sum_{\substack{v, \Delta \\ 0 < |v\Delta| \le R^2 Q^2 P^{\varepsilon - 2} \\ \times \sum_{\substack{B_1, B_2 \\ (4.10)}} (|v|R^{-2} P^{2-\varepsilon} (\Delta G_1 G_2)^{-1})^{-1} G_2}.
$$

Recalling (4.14), we arrive at

(4.16)
$$
\mathcal{F}(G_1, G_2) \ll P^{-4+\epsilon} R^4 Q^2 G_1^{1/2} G_2^{1/2} \ll P^{-4+\epsilon} R^4 Q^2 H.
$$

We choose

$$
H = R^{4/5} Q^{4/5}
$$

;

by equating $R^6 Q^4 P^{-4} H^{-3/2} = P^{-4} R^4 Q^2 H$, to conclude finally

$$
(4.17) \t\t \mathcal{F}(G_1, G_2) \ll P^{-4+\varepsilon} Q^3 R^2 + P^{-4+\varepsilon} Q^{14/5} R^{24/5}.
$$

The proof is completed by putting (4.17) into (4.9).

5. Invoking the square sieve

By the dyadic argument, our task is to prove

(5.1)
$$
\sum_{k \leq P} \left| \sum_{D'_i \leq d_i < 2D'_i} \beta(\mathbf{d}) (\Omega_{\mathbf{d}}(N - k^2) - \mathcal{M}_{\mathbf{d}}, \varrho(N - k^2)) \right| \ll P^{2-\varepsilon}.
$$

Suppose that $\kappa \in (0, 1/2)$. Set $m = 4\lceil \kappa^{-1} \rceil$, and denote by \mathcal{R}_j the interval $[2^{j-1}P^{\kappa}, 2^j P^{\kappa}]$ for $1 \le j \le m$. Let $\pi(\mathcal{R}) = \prod_{p \in \mathcal{R}} p$. We have the partitions

$$
[D'_i, 2D'_i) = \bigsqcup_{J \subseteq \{1,\dots,m\}} \mathcal{D}_J,
$$

where $\mathcal{D}_J = \{D'_i \leq d_i < 2D'_i : (d_i, \pi(\mathcal{R}_j)) \neq 1 \Longleftrightarrow j \in J\}$. Hence (5.1) can be deduced from

$$
\sum_{k \leq P} \left| \sum_{d_i \in \mathcal{D}_{J_i} (1 \leq i \leq 3)} \beta(\mathbf{d}) (\Omega_{\mathbf{d}}(N - k^2) - \mathcal{M}_{\mathbf{d}, Q}(N - k^2)) \right| \ll P^{2-\varepsilon}.
$$

By Cauchy's inequality, it suffices to prove

$$
(5.2) \qquad \sum_{k\leq P} \left| \sum_{d_i \in \mathcal{D}_{J_i}} \beta(\mathbf{d}) (\Omega_{\mathbf{d}}(N-k^2) - \mathcal{M}_{\mathbf{d},Q}(N-k^2)) \right|^2 \ll P^{3-\varepsilon}.
$$

Note that $D_i' \leq D_i \leq P^{1/2} < P$. So if \mathcal{D}_J is non-empty, then $|J| \leq m/4$. Therefore for any triple $\mathcal{D}_{J_1}, \mathcal{D}_{J_2}, \mathcal{D}_{J_3}$ satisfying $\mathcal{D}_{J_i} \neq \emptyset$ ($1 \leq i \leq 3$), there exists $1 \leq j \leq m$ such that $j \notin J_1 \cup J_2 \cup J_3$. In other words, we have $(p, d_i) = 1$ for all $p \in \mathcal{R}_j$ and $d_i \in \mathcal{D}_{J_i}$.

 \Box

In view of the square sieve of Heath-Brown [8] and the above preparations, Proposition 4 can be reduced to the estimate

$$
(5.3) \quad \mathcal{E}_0 = \sum_{1 \le n < N} \left| \sum_{\mathbf{d}} \beta(\mathbf{d}) (\Omega_{\mathbf{d}}(n) - \mathcal{M}_{\mathbf{d}, Q}(n)) \right|^2 \left(\frac{\log R}{R} \sum_{\substack{p \ne N \\ R \le p < 2R}} \left(\frac{N - n}{p} \right) \right)^2
$$
\n
$$
\ll P^{4 + \varepsilon} R^{-1} Q^{-1} + (D_1 D_2 D_3)^2 P^{2 + \varepsilon} R^3 + P^{\varepsilon} Q^{14/5} R^{29/5},
$$

where β (**d**) is supported on $d_i \in \mathcal{D}_i \subseteq [D_i, 2D_i)$, $1 \le i \le 3$, satisfying (2.6), (2.7), (2.8), and

$$
(d_1 d_2 d_3, p) = 1
$$
 for all $d_i \in \mathcal{D}_i$, $R \le p < 2R$,

and R is restricted by

(5.4)
$$
P^{1+\varepsilon}Q^{-1} < R < P^{2-\varepsilon}Q^{-2}.
$$

Although our choices will be of type $Q^{1-\epsilon}$ and $R = P^{\epsilon}$, there is really some space for the parameters Q and R so that $\mathcal{E}_0 \ll P^{3-\epsilon}$ and (5.4) hold simultaneously.

6. Proof of Proposition 4

We start to estimate ε_0 which is bounded by

(6.1)
$$
\mathcal{E}_0 \ll \frac{\log^2 R}{R^2} |\mathcal{E}_1| + \frac{\log R}{R} \mathcal{E}_2,
$$

where

$$
\mathcal{E}_1 = \sum_{\mathcal{R}} \left(\frac{N-n}{pp'} \right) \sum_{1 \le n < N} \left| \sum_{\mathbf{d}} \beta(\mathbf{d}) \left(\Omega_{\mathbf{d}}(n) - \mathcal{M}_{\mathbf{d}}, Q(n) \right) \right|^2
$$

and

$$
\mathcal{E}_2 = \sum_{1 \leq n < N} \bigg| \sum_{\mathbf{d}} \beta(\mathbf{d}) \bigg(\Omega_{\mathbf{d}}(n) - \mathcal{M}_{\mathbf{d}}, \varrho(n) \bigg) \bigg|^2.
$$

Throughout, we use $\sum_{\mathcal{R}}$ to indicate that the summation is taken over prime numbers p, p' with $R \le p \ne p' < 2R$ and $(p p', N) = 1$.

We expand the square to obtain

(6.2)
$$
\mathcal{E}_2 = \mathcal{E}_2^{(1)} - 2\mathcal{E}_2^{(2)} + \mathcal{E}_2^{(3)},
$$

where

$$
(6.3) \t\t \t\t \t\t \mathcal{E}
$$

$$
\mathcal{E}_2^{(i)} = \sum_{\mathbf{d}} \sum_{\mathbf{t}} \beta(\mathbf{d}) \beta(\mathbf{t}) J_2^{(i)}
$$

with

$$
J_2^{(1)} = \int_0^1 f_{\mathbf{d}}(\alpha) f_{\mathbf{t}}(-\alpha) d\alpha,
$$

\n
$$
J_2^{(2)} = \int_0^1 f_{\mathbf{d}}(\alpha) W_{\mathbf{t},Q}(-\alpha) d\alpha,
$$

\n
$$
J_2^{(3)} = \int_0^1 W_{\mathbf{d},Q}(\alpha) W_{\mathbf{t},Q}(-\alpha) d\alpha.
$$

Let

$$
\mathcal{T}_2(q,\mathbf{d},\mathbf{t},\mathbf{n},\mathbf{l}) = \sum_{a(q)^*} \int_{\mathcal{B}(q,a)} S_{\mathbf{d}}(q,a,\mathbf{n}) S_{\mathbf{t}}(q,-a,-\mathbf{l}) I_{\mathbf{d}}\left(\beta N, -\frac{P}{q}\mathbf{n}\right) I_{\mathbf{t}}\left(-\beta N, \frac{P}{q}\mathbf{l}\right) d\beta,
$$

where

$$
\mathcal{B}(q,a) = \left[-\frac{1}{q(q+q')}, \frac{1}{q(q+q'')} \right]
$$

with q' and q'' satisfying

$$
P < q + q', q + q'' \le q + P
$$
, $aq' \equiv 1 \pmod{q}$, $aq'' \equiv -1 \pmod{q}$.

Set

$$
\mathcal{T}_2(q,\mathbf{d},\mathbf{t}) = \mathcal{T}_2(q,\mathbf{d},\mathbf{t},\mathbf{0},\mathbf{0}).
$$

By Lemma 6, we have

$$
J_2^{(3)} = \sum_{q \le P} \sum_{a(q)^*} \int_{\beta \in \mathcal{B}(q,a)} \mathcal{W}_{d,Q} \left(\frac{a}{q} + \beta\right) \mathcal{W}_{t,Q} \left(-\frac{a}{q} - \beta\right) d\beta
$$

=
$$
\frac{P^6}{d_1 d_2 d_3 t_1 t_2 t_3} \sum_{q \le Q} \frac{1}{q^6} \mathcal{T}_2(q, \mathbf{d}, \mathbf{t}) + O(P^{-A}).
$$

So

(6.4)
$$
\mathcal{E}_2^{(3)} = \mathcal{E}_2'(Q) + O(P^{-A}),
$$

where

(6.5)
$$
\mathcal{E}'_2(K) = P^6 \sum_{\mathbf{d}} \sum_{\mathbf{t}} \frac{\beta(\mathbf{d}) \beta(\mathbf{t})}{d_1 d_2 d_3 t_1 t_2 t_3} \sum_{q \le K} \frac{1}{q^6} \mathcal{T}_2(q, \mathbf{d}, \mathbf{t}).
$$

According to Lemma 5, one has

(6.6)
$$
J_2^{(1)} = \frac{P^6}{d_1d_2d_3t_1t_2t_3} \sum_{q \leq P} \frac{1}{q^6} \sum_{\mathbf{n} \in \mathcal{N}_{\mathbf{d},q}} \sum_{\mathbf{l} \in \mathcal{N}_{\mathbf{t},q}} \mathcal{T}_2(q, \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}) + O(P^{-A}).
$$

Combining Lemma 5 and Lemma 6, we derive

(6.7)
$$
J_2^{(2)} = \frac{P^6}{d_1 d_2 d_3 t_1 t_2 t_3} \sum_{q \le Q} \frac{1}{q^6} \sum_{\mathbf{n} \in \mathcal{N}_{\mathbf{d},q}} \mathcal{T}_2(q, \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{0}) + O(P^{-A}).
$$

We exchange the summation over a and the integration by the standard technique to get

$$
(6.8) \quad \mathcal{T}_2(q, \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}) = \int_{|\beta| \leq \frac{1}{qP}} \sum_{|v| \leq P} \sigma(v; \beta, q) \sum_{a(q)^*} e_q(\overline{a}v) S_{\mathbf{d}}(q, a, \mathbf{n}) S_{\mathbf{t}}(q, -a, -\mathbf{l})
$$

$$
\times I_{\mathbf{d}} \left(\beta N, -\frac{P}{q}\mathbf{n}\right) I_{\mathbf{t}} \left(-\beta N, \frac{P}{q}\mathbf{l}\right) d\beta,
$$

where the function σ satisfies $\sigma(v;\beta,q) \ll 1/(1+|v|)$. For this technique, one may refer to [9, (98) and (99)], for example. One can also refer to Estermann [5, proof of Lemma 13].

Recalling (4.1), we have

(6.9)
$$
\mathcal{T}_2(q, \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}) \ll \sum_{|v| \leq P} \frac{1}{1+|v|} \int_{|\beta| \leq \frac{1}{qP}} |\theta(q; \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, v, 1, 1)|
$$

$$
\times \left| I_{\mathbf{d}} \left(\beta N, -\frac{P}{q} \mathbf{n} \right) I_{\mathbf{t}} \left(-\beta N, \frac{P}{q} \mathbf{l} \right) \right| d\beta
$$

$$
\leq \sum_{|v| \leq P} \frac{1}{1+|v|} |\theta(q; \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, v, 1, 1)| d_2(q, \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}),
$$

where

$$
\mathcal{J}_2(q, \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}) = \int_{-\infty}^{\infty} \left| I_{\mathbf{d}}\left(\beta N, -\frac{P}{q}\mathbf{n}\right) I_{\mathbf{t}}\left(-\beta N, \frac{P}{q}\mathbf{l}\right) \right| d\beta.
$$

Let

$$
\mathcal{X}_2 = P^6 \sum_{|v| \le P} \frac{1}{1+|v|} \sum_{\mathbf{d}, \mathbf{t}} \frac{|\beta(\mathbf{d})\beta(\mathbf{t})|}{d_1 d_2 d_3 t_1 t_2 t_3} \times \sum_{q \le P} \frac{1}{q^6} \sum_{\mathbf{n} \in \mathcal{N}_{\mathbf{d},q}, \mathbf{l} \in \mathcal{N}_{\mathbf{t},q}} |\theta(q; \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, v, 1, 1)| \mathcal{J}_2(q, \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}).
$$

By (6.3), (6.5), (6.6) and (6.9), we get

(6.10)
$$
\mathcal{E}_2^{(1)} = \mathcal{E}_2'(P) + O(\mathcal{X}_2) + O(P^{-A}).
$$

Similarly from (6.3) , (6.5) , (6.7) and (6.9) we deduce that

(6.11)
$$
\mathcal{E}_2^{(2)} = \mathcal{E}_2'(Q) + O(\mathcal{X}_2) + O(P^{-A}).
$$

One has, by Lemma 1,

$$
\sum_{a(q)^*} \int_{\beta \in \mathcal{B}(q,a)} S_{\mathbf{d}}(q,a) S_{\mathbf{t}}(q,-a) |I(\beta N)|^6 d\beta \ll P^{-2} q^4 (q,\mathbf{d}^2)^{1/2} (q,\mathbf{t}^2)^{1/2}.
$$

This yields

$$
(6.12) \quad \mathcal{E}'_2(P) - \mathcal{E}'_2(Q) \ll P^4 \sum_{\mathbf{d}} \sum_{\mathbf{t}} \frac{|\beta(\mathbf{d})\beta(\mathbf{t})|}{d_1 d_2 d_3 t_1 t_2 t_3} \sum_{Q < q \le P} \frac{1}{q^2} (q, \mathbf{d}^2)^{1/2} (q, \mathbf{t}^2)^{1/2} \ll Q^{-1} P^{4+\varepsilon}.
$$

We conclude from (6.2), (6.4), (6.10), (6.11) and (6.12) that

$$
\varepsilon_2 \ll Q^{-1} P^{4+\varepsilon} + \mathcal{X}_2.
$$

From Lemma 4 (i),

$$
\mathcal{J}_2(q, \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}) \ll P^{-2+\varepsilon} \min \left\{ \frac{q^2}{P^2} \left(\sum_{j=1}^3 \left(\frac{|n_j|}{d_j} + \frac{|l_i|}{t_i} \right) \right)^{-2}, \frac{q}{P} \left(\sum_{j=1}^3 \left(\frac{|n_j|}{d_j} + \frac{|l_i|}{t_i} \right) \right)^{-1} \right\}.
$$

Applying Lemma 14, we see that

$$
\mathcal{X}_2 \ll P^{4+\varepsilon} (D_1 D_2 D_3)^{-2} \mathcal{Y}_2 \ll P^{3+\varepsilon} + (D_1 D_2 D_3)^2 P^{2+\varepsilon}.
$$

Hence our final estimate for ε_2 is

(6.13)
$$
\mathcal{E}_2 \ll P^{4+\varepsilon} Q^{-1} + (D_1 D_2 D_3) P^{2+\varepsilon}.
$$

Now we consider ε_1 . Following the argument in [9, Section 3.4.1], we arrive at

(6.14)
$$
\mathcal{E}_1 = \mathcal{E}_1^{(1)} - 2\mathcal{E}_1^{(2)} + \mathcal{E}_1^{(3)},
$$

where

(6.15)
$$
\mathcal{E}_1^{(i)} = \sum_{\mathcal{R}} \frac{\gamma(pp')}{pp'} \sum_{\mathbf{d}} \sum_{\mathbf{t}} \beta(\mathbf{d}) \beta(\mathbf{t}) \sum_{s(pp')^*} \left(\frac{s}{pp'}\right) e_{pp'}(-sN) J_1^{(i)}
$$

with

$$
J_1^{(1)} = \int_0^1 f_{\mathbf{d}} \left(\alpha + \frac{s}{pp'} \right) f_{\mathbf{t}}(-\alpha) d\alpha,
$$

\n
$$
J_1^{(2)} = \int_0^1 f_{\mathbf{d}} \left(\alpha + \frac{s}{pp'} \right) W_{\mathbf{t},Q}(-\alpha) d\alpha,
$$

\n
$$
J_1^{(3)} = \sum_{n \in \mathbb{Z}} \mathcal{M}_{\mathbf{d},Q}(n) \mathcal{M}_{\mathbf{t},Q}(n) e_{pp'}(sn).
$$

We decompose the integral

$$
J_1^{(1)} = \sum_{q \le P} \sum_{a(q)^*} \int_{\beta \in \mathcal{B}(q,a)} f_{\mathbf{d}} \left(\beta + \frac{a}{q} + \frac{s}{pp'} \right) f_{\mathbf{t}} \left(-\beta - \frac{a}{q} \right) d\beta
$$

=
$$
\sum_{q \le P} \sum_{\Delta} \sum_{\substack{a(q)^* \\ (app' + sq, app') = \Delta}} \int_{\mathcal{B}(q,a)} f_{\mathbf{d}} \left(\beta + \frac{(app' + sq)\Delta^{-1}}{app'\Delta^{-1}} \right) f_{\mathbf{t}} \left(-\beta - \frac{a}{q} \right) d\beta.
$$

Note that $(app' + sq, app') | (pp')^2$, we deduce by Lemma 5

$$
J_1^{(1)} = \sum_{\Delta \mid (pp')^2} \sum_{q \leq P} \frac{P^6 \Delta^3}{q^6 d_1 d_2 d_3 t_1 t_2 t_3 (pp')^3}
$$

\$\times \sum_{\mathbf{n} \in \mathcal{N}_{\mathbf{d},q}(pp'/\Delta)} \sum_{\mathbf{l} \in \mathcal{N}_{\mathbf{t},q}} \sum_{\substack{a(q)^* \\ (app'+sq,app') = \Delta}} \int_{\mathcal{B}(q,a)} S_{\mathbf{d}} \left(\frac{app'}{\Delta}, \frac{app'+sq}{\Delta}, \mathbf{n} \right) \times S_{\mathbf{t}}(q, -a, -1) I_{\mathbf{d}} \left(\beta N, -\frac{P\Delta}{app'} \mathbf{n} \right) I_{\mathbf{t}} \left(-\beta N, \frac{P}{q} \mathbf{l} \right) d\beta + O(P^{-A}).

Let

$$
\mathcal{T}_1(q, \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, p, p', \Delta) = \sum_{s(pp')^*} \left(\frac{s}{pp'}\right) e_{pp'}(-sN) \sum_{a(q)^*} \int_{\mathcal{B}(q, a)} S_{\mathbf{d}}\left(\frac{qp'p'}{\Delta}, \frac{app'+sq}{\Delta}, \mathbf{n}\right)
$$

$$
\times S_{\mathbf{t}}(q, -a, -\mathbf{l}) I_{\mathbf{d}}\left(\beta N, -\frac{P\Delta}{qpp'}\mathbf{n}\right) I_{\mathbf{t}}\left(-\beta N, \frac{P}{q}\mathbf{l}\right) d\beta,
$$

and let

$$
\mathcal{T}_1(q,\mathbf{d},\mathbf{t},p,p',\Delta)=\mathcal{T}_1(q,\mathbf{d},\mathbf{t},\mathbf{0},\mathbf{0},p,p',\Delta).
$$

From above we obtain

$$
(6.16) \quad \mathcal{E}_1^{(1)} = P^6 \sum_{\mathcal{R}} \frac{\gamma(pp')^4}{(pp')^4} \sum_{\mathbf{d},\mathbf{t}} \frac{\beta(\mathbf{d})\beta(\mathbf{t})}{d_1 d_2 d_3 t_1 t_2 t_3}
$$

$$
\times \sum_{\Delta \mid (pp')^2} \sum_{q \leq P} \frac{\Delta^3}{q^6} \sum_{\mathbf{n} \in \mathcal{N}_{\mathbf{d},q}(pp'/\Delta)} \sum_{\mathbf{l} \in \mathcal{N}_{\mathbf{t},q}} \mathcal{T}_1(q, \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, p, p', \Delta).
$$

By interchanging the summation over a and the integration, we see that $\mathcal{T}_1(q, \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, p, p', \Delta)$ is equal to

$$
\int_{|\beta| \leq \frac{1}{qP}} \sum_{|v| \leq P} \sigma(v; q, \beta) \sum_{\substack{a(q)^* \\ (app'+sq,app') = \Delta}} e_q(\overline{a}v) S_d \left(\frac{app' + sq}{\Delta}, \frac{app' + sq}{\Delta}, \mathbf{n} \right) S_t(q, -a, -1)
$$
\n
$$
\times I_d \left(\beta N, -\frac{P\Delta}{app'} \mathbf{n} \right) I_t \left(-\beta N, \frac{P}{q} \mathbf{l} \right) d\beta.
$$

Recalling the definition of $W(\Delta, q; \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, p, p', v)$, we have

(6.17)
$$
\mathcal{T}_1(q, \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, p, p', \Delta)
$$

$$
\ll \sum_{|v| \leq P} \frac{1}{1+|v|} |W(\Delta, q; \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, p, p', v)| \mathcal{J}_1\left(q, \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, \frac{pp'}{\Delta}\right),
$$

where

$$
\mathcal{J}_1(q, \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, H) = \int_{-\infty}^{\infty} \left| I_{\mathbf{d}} \left(\beta N, -\frac{P}{qH} \mathbf{n} \right) I_{\mathbf{t}} \left(-\beta N, \frac{P}{q} \mathbf{l} \right) \right| d\beta.
$$

To discuss the contribution from $(n, l) = 0 \in \mathbb{Z}^6$, we define

$$
\mathcal{T}'_1(q, \mathbf{d}, \mathbf{t}, p, p', \Delta) = \sum_{s(pp')^*} \left(\frac{s}{pp'}\right) e_{pp'}(-sN)
$$

\$\times \sum_{a(q)^*} \int_{|\beta| \le \frac{1}{2qP}} S_d\left(\frac{qp'p'}{\Delta}, \frac{app' + sq}{\Delta}\right) S_t(q, -a) |I(\beta)|^6 d\beta\$
= $W(\Delta, q; \mathbf{d}, \mathbf{t}, \mathbf{0}, \mathbf{0}, p, p', 0) \int_{|\beta| \le \frac{1}{2qP}} |I(\beta)|^6 d\beta.$

We deduce from Lemma 4 (ii) that

(6.18)
$$
\mathcal{T}'_1(q, \mathbf{d}, \mathbf{t}, p, p', \Delta) - \mathcal{T}_1(q, \mathbf{d}, \mathbf{t}, p, p', \Delta)
$$

$$
\ll P^{-4}q^2 \sum_{|v| \leq P} \frac{1}{1+|v|} |W(\Delta, q; \mathbf{d}, \mathbf{t}, \mathbf{0}, \mathbf{0}, p, p', v)|
$$

and

(6.19)
$$
T'_1(q, \mathbf{d}, \mathbf{t}, p, p', \Delta) - \sigma_0 P^{-2} W(\Delta, q; \mathbf{d}, \mathbf{t}, 0, 0, p, p', 0) \ll P^{-4} q^2 |W(\Delta, q; \mathbf{d}, \mathbf{t}, 0, 0, p, p', 0)|.
$$

Let

$$
\mathcal{E}'_1(K) = \sigma_0 P^4 \sum_{\mathcal{R}} \frac{\gamma(pp')}{(pp')^4} \sum_{\mathbf{d},\mathbf{t}} \frac{\beta(\mathbf{d})\beta(\mathbf{t})}{d_1 d_2 d_3 t_1 t_2 t_3} \sum_{\Delta \, | \, (pp')^2} \sum_{q \leq K} \frac{\Delta^3}{q^6} W(\Delta, q; \mathbf{d}, \mathbf{t}, \mathbf{0}, \mathbf{0}, p, p', 0),
$$

and define

$$
\mathcal{X}_1 = P^4 R^{-7} \sum_{\mathcal{R}} \sum_{|v| \leq P} \frac{1}{1+|v|} \sum_{\mathbf{d}, \mathbf{t}} \frac{|\beta(\mathbf{d})\beta(\mathbf{t})|}{d_1 d_2 d_3 t_1 t_2 t_3} \sum_{\Delta \mid (pp')^2} \sum_{q \leq P} \frac{\Delta^3}{q^6}
$$

$$
\times \sum_{\mathbf{n} \in \mathcal{N}_{\mathbf{d}, q}(pp'/\Delta)} \sum_{\mathbf{l} \in \mathcal{N}_{\mathbf{t}, q}} |W(\Delta, q; \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, p, p', v)| \mathcal{C}\bigg(q, \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, \frac{pp'}{\Delta}\bigg).
$$

Here the function $\mathcal{C}(q, \mathbf{d}, \mathbf{t}, \mathbf{n}, \mathbf{l}, pp'/\Delta)$ is defined in (4.6). By Lemma 4 (i), if $(\mathbf{n}, \mathbf{l}) \neq \mathbf{0} \in \mathbb{Z}^6$, then

(6.20)
$$
\mathcal{J}_1\left(q,\mathbf{d},\mathbf{t},\mathbf{n},\mathbf{l},\frac{pp'}{\Delta}\right) \ll P^{-2+\varepsilon} \mathcal{C}\left(q,\mathbf{d},\mathbf{t},\mathbf{n},\mathbf{l},\frac{pp'}{\Delta}\right).
$$

We conclude from (6.16), (6.17), (6.18), (6.19) and (6.20) that

(6.21)
$$
\mathcal{E}_1^{(1)} = \mathcal{E}_1'(P) + O(\mathcal{X}_1) + O(P^{-A}).
$$

Similarly we can also obtain

(6.22)
$$
\mathcal{E}_1^{(2)} = \mathcal{E}_1'(Q) + O(\mathcal{X}_1) + O(P^{-A}).
$$

We shall prove

(6.23)
$$
\mathcal{E}_1^{(3)} = \mathcal{E}_1' + O(P^{\varepsilon} Q^3 R^3) + O(P^{\varepsilon} Q^{14/5} R^{29/5}),
$$

where

$$
\mathcal{E}'_1 = \sigma_0 P^4 \sum_{\mathcal{R}} \frac{\gamma(pp')}{(pp')^4} \sum_{\mathbf{d},\mathbf{t}} \frac{\beta(\mathbf{d})\beta(\mathbf{t})}{d_1 d_2 d_3 t_1 t_2 t_3} \times \sum_{\Delta \mid (pp')^2} \frac{\Delta^3}{q \le \min\{Q, Q\Delta(pp')^{-1}\}} \frac{1}{q^6} W(\Delta, q; \mathbf{d}, \mathbf{t}, \mathbf{0}, \mathbf{0}, p, p', 0).
$$

Note that $\min\{Q, Q\Delta(pp')^{-1}\}\leq Q < P$, we introduce

$$
\mathcal{X}_3 = P^4 R^{-7} \sum_{\mathcal{R}} \sum_{\mathbf{d}, \mathbf{t}} \frac{|\beta(\mathbf{d})\beta(\mathbf{t})|}{d_1 d_2 d_3 t_1 t_2 t_3} \times \sum_{\Delta \mid (pp')^2 \min\{Q, Q\Delta(pp')^{-1}\} \le q \le P} \frac{\Delta^3}{q^6} |W(\Delta, q; \mathbf{d}, \mathbf{t}, \mathbf{0}, \mathbf{0}, p, p', 0)|.
$$

Thus by (6.14), (6.21), (6.22) and (6.23) we arrive at

$$
\mathcal{E}_1 \ll O(\mathcal{X}_1) + O(\mathcal{X}_3) + O(P^{\varepsilon} Q^3 R^3) + O(P^{\varepsilon} Q^{14/5} R^{29/5}).
$$

By Lemma 14, we have

$$
\mathcal{X}_1 \ll P^{4+\varepsilon} R^{-7} (D_1 D_2 D_3)^{-2} \sum_{\mathcal{R}} \mathcal{Y}_1 \ll P^{3+\varepsilon} R + (D_1 D_2 D_3)^2 P^{2+\varepsilon} R^5.
$$

From Lemma 11,

(6.24)
$$
W(\Delta, q; \mathbf{d}, \mathbf{t}, \mathbf{0}, \mathbf{0}, p, p', v) \ll 2^{4u} r^4 (r, \mathbf{d}^2)^{1/2} (r, \mathbf{t}^2)^{1/2} \Delta^{-2} R^4 (\pi \pi')^5 (1 + \Delta R^{-2})^{-1}.
$$

Substituting (6.24) into the definition of \mathcal{X}_3 , we can deduce that

$$
\mathcal{X}_3 \ll P^4 R^{-3} \sum_{\mathcal{R}} \sum_{\mathbf{d},\mathbf{t}} \frac{|\beta(\mathbf{d})\beta(\mathbf{t})|}{d_1 d_2 d_3 t_1 t_2 t_3} \times \sum_{\Delta \mid (pp')^2} \sum_{\min\{Q, Q\Delta(pp')^{-1}\} \le 2^u \pi \pi' r} \frac{\Delta(r, \mathbf{d}^2)^{1/2} (r, \mathbf{t}^2)^{1/2}}{2^{2u} \pi \pi' r^2 (1 + \Delta R^{-2})} \ll P^{4+\varepsilon} R^{-3} \sum_{\mathcal{R}} \sum_{\Delta \mid (pp')^2} \Delta \min\{Q, Q\Delta(pp')^{-1}\}^{-1} (1 + \Delta R^{-2})^{-1} \ll P^{4+\varepsilon} R Q^{-1}.
$$

Thus for ε_1 we finally obtain

(6.25)
$$
\mathcal{E}_1 \ll P^{4+\varepsilon} R Q^{-1} + (D_1 D_2 D_3)^2 P^{2+\varepsilon} R^5 + P^{\varepsilon} Q^{14/5} R^{29/5}.
$$

Combining (6.13), (6.25) and the lines around (5.3) and (6.1), we established Proposition 4.

We are left to establish (6.23). Recalling the definition of $J_1^{(3)}$ $\binom{3}{1}$, one has

$$
J_1^{(3)} = \frac{P^2}{d_1 d_2 d_3 t_1 t_2 t_3} \sum_{q_1, q_2 \le Q} (q_1 q_2)^{-3} \sum_{\substack{a_1(q_1)^* \\ a_2(q_2)^*}} S_{\mathbf{d}}(q_1, -a_1) S_{\mathbf{t}}(q_2, -a_2)
$$

$$
\times \sum_{n \in \mathbb{Z}} H^2\left(\frac{n}{N}\right) e\left(n\left(\frac{a_1}{q_1} + \frac{a_2}{q_2} + \frac{s}{pp'}\right)\right).
$$

By Lemma 7, we get

(6.26)
$$
\mathcal{E}_1^{(3)} = \mathcal{E}_1'' + E + O(P^{-A}),
$$

where

$$
\mathcal{E}_{1}^{"} = \sigma_{0} P^{4} \sum_{\mathcal{R}} \frac{\gamma(pp')}{pp'} \sum_{\mathbf{d}} \sum_{\mathbf{t}} \frac{\beta(\mathbf{d})\beta(\mathbf{t})}{d_{1}d_{2}d_{3}t_{1}t_{2}t_{3}} \sum_{s(pp')^{*}} \left(\frac{s}{pp'}\right) e_{pp'}(-sN)
$$

$$
\times \sum_{q_{1},q_{2} \leq Q} (q_{1}q_{2})^{-3} \sum_{\substack{a_{1}(q_{1})^{*}, a_{2}(q_{2})^{*} \\ \frac{a_{1}}{q_{1}} + \frac{a_{2}}{q_{2}} + \frac{s}{pp'} \in \mathbb{Z}} S_{\mathbf{d}}(q_{1}, -a_{1}) S_{\mathbf{t}}(q_{2}, -a_{2})
$$

and

$$
E = \sum_{\mathcal{R}} \frac{\gamma(pp')}{pp'} \sum_{\mathbf{d}, \mathbf{t}} \frac{P^2 \beta(\mathbf{d}) \beta(\mathbf{t})}{d_1 d_2 d_3 t_1 t_2 t_3} \sum_{n \in \mathbb{Z}} H^2\left(\frac{n}{N}\right) \sum_{s(pp')^*} \left(\frac{s}{pp'}\right) e_{pp'}(-sN) \sum_{q_1, q_2 \le Q} \frac{1}{q_1^3 q_2^3}
$$

$$
\times \sum_{\substack{a_1(q_1)^*, a_2(q_2)^*\\0 < |\frac{a_1}{q_1} + \frac{a_2}{q_2} + \frac{s}{pp'}| \le P^{\varepsilon - 2}}} S_{\mathbf{d}}(q_1, -a_1) S_{\mathbf{t}}(q_2, -a_2) e\left(n\left(\frac{a_1}{q_1} + \frac{a_2}{q_2} + \frac{s}{pp'}\right)\right).
$$

Notice that

$$
\frac{a_1}{q_1} + \frac{a_2pp' + sq_2}{q_2pp'} = \frac{a_1}{q_1} + \frac{a_2}{q_2} + \frac{s}{pp'} \in \mathbb{Z}
$$

is equivalent to

$$
q_1 = q_2 pp' \Delta^{-1}
$$
 and $-a_1 \equiv (a_2 pp' + sq_2) \Delta^{-1}$ (mod q_1),

where $\Delta = (a_2 pp' + sq_2, q_2pp')$. Hence

$$
\mathcal{E}_1^{\prime\prime} = \mathcal{E}_1^{\prime}.
$$

Now we handle E . By Lemma 1 (vi),

(6.28)
$$
E \ll P^4 R \sup_{n,p,p'} \sum_{\mathbf{d}} \sum_{\mathbf{t}} \frac{|\beta(\mathbf{d})\beta(\mathbf{t})|}{d_1 d_2 d_3 t_1 t_2 t_3} |\mathcal{F}|,
$$

where

$$
\mathcal{F} := \sum_{s(pp')^*} \left(\frac{s}{pp'}\right) e_{pp'}(-sN) \sum_{q_1, q_2 \le Q} (q_1q_2)^{-3}
$$

$$
\times \sum_{\substack{a_1(q_1)^*, a_2(q_2)^*\\0 < \|\frac{a_1}{q_1} + \frac{a_2}{q_2} + \frac{s}{pp'}\| \le P^{\varepsilon - 2}}} S_{\mathbf{d}}(q_1, -a_1) S_{\mathbf{t}}(q_2, -a_2) e\left(n\left(\frac{a_1}{q_1} + \frac{a_2}{q_2} + \frac{s}{pp'}\right)\right).
$$

Note that

$$
\frac{a_1}{q_1} + \frac{a_2}{q_2} + \frac{s}{pp'} = \frac{pp'(a_1q_2 + a_2q_1) + sq_1q_2}{q_1q_2pp'}.
$$

We divide the summations according to $pp'(a_1q_2 + a_2q_1) + sq_1q_2 \pmod{q_1q_2pp'}$,

$$
\mathcal{F} = \sum_{0 < |l| \le R^2 Q^2 P^{\varepsilon - 2}} \sum_{s(pp')^*} \left(\frac{s}{pp'} \right) e_{pp'}(-sN) \sum_{\substack{q_1, q_2 \le Q \\ |l|(pp')^{-1} P^{2-\varepsilon} < q_1 q_2}} (q_1 q_2)^{-3}
$$
\n
$$
\times \sum_{\substack{a_1(q_1)^*, a_2(q_2)^* \\ ap'(a_1 q_2 + a_2 q_1) + sq_1 q_2 \equiv l \pmod{q_1 q_2 pp'}}} S_{\mathbf{d}}(q_1, -a_1) S_{\mathbf{t}}(q_2, -a_2)
$$
\n
$$
\times e \left(n \left(\frac{a_1}{q_1} + \frac{a_2}{q_2} + \frac{s}{pp'} \right) \right).
$$
\n(4.14)

Here the restriction $0 < |l| \leq R^2 Q^2 P^{\varepsilon - 2}$ and $|l| (pp')^{-1} P^{2-\varepsilon} < q_1 q_2$ come from

$$
0 < \left\| \frac{a_1}{q_1} + \frac{a_2}{q_2} + \frac{s}{pp'} \right\| \le P^{\varepsilon - 2}.
$$

The congruence $pp'(a_1q_2 + a_2q_1) + sq_1q_2 \equiv l \pmod{q_1q_2pp'}$ implies

$$
e\left(n\left(\frac{a_1}{q_1} + \frac{a_2}{q_2} + \frac{s}{pp'}\right)\right) = e\left(\frac{ln}{q_1q_2pp'}\right).
$$

Thus

$$
\mathcal{F} = \sum_{0 < |l| \le R^2 Q^2 P^{\varepsilon - 2}} \sum_{s(pp')^*} \left(\frac{s}{pp'} \right) e_{pp'}(-sN) \sum_{\substack{q_1, q_2 \le Q \\ |l|(pp')^{-1} P^{2-\varepsilon} < q_1 q_2}} (q_1 q_2)^{-3}
$$
\n
$$
\times e \left(\frac{\ln}{q_1 q_2 p p'} \right) \sum_{\substack{a_1(q_1)^*, a_2(q_2)^* \\ ap'(a_1 q_2 + a_2 q_1) + sq_1 q_2 \equiv l \pmod{q_1 q_2 pp'}}} S_{\mathbf{d}}(q_1, -a_1) S_{\mathbf{t}}(q_2, -a_2).
$$

Recall the assumption (5.4), we easily know $(l, pp') = 1$. This implies $(q_1q_2, pp') = 1$. So

$$
pp'(a_1q_2 + a_2q_1) + sq_1q_2 \equiv l \pmod{q_1q_2pp'}
$$

is equivalent to

$$
pp'(a_1q_2 + a_2q_1) \equiv l \pmod{q_1q_2}
$$
 and $sq_1q_2 \equiv l \pmod{pp'}$.

Thus

$$
\mathcal{F} = \sum_{0 < |l| \le R^2 Q^2 P^{\varepsilon - 2}} \sum_{\substack{q_1, q_2 \le Q \\ |l| (pp')^{-1} P^{2-\varepsilon} < q_1 q_2}} (q_1 q_2)^{-3} \left(\frac{q_1 q_2 l}{p p'} \right) e_{pp'} (-\overline{q_1 q_2} l N)
$$
\n
$$
\times e \left(\frac{l n}{q_1 q_2 p p'} \right) \sum_{\substack{a_1 (q_1)^*, a_2 (q_2)^* \\ p p'(a_1 q_2 + a_2 q_1) \equiv l \pmod{q_1 q_2}}} S_{\mathbf{d}}(q_1, -a_1) S_{\mathbf{t}}(q_2, -a_2).
$$

Now (6.23) follows from Lemma 15, (6.26), (6.27) and (6.28). The proof of Proposition 4 is complete.

7. Proof of Proposition 3

Let us define

$$
\widetilde{\mathcal{H}}(D_1, D_2, D_3) = \sum_{\substack{d_i \le D_i \ (1 \le i \le 3) \\ (d_i, d_j) \le P^{\varepsilon} \ (1 \le i < j \le 3)}} \beta(\mathbf{d}) \bigg(\mathcal{L}_{\mathbf{d}}(N) - \frac{\mathcal{N}_0(N) \Sigma_0(\mathbf{d}, N)}{d_1 d_2 d_3} \bigg),
$$

where $\beta(\mathbf{d}) = \beta(d_1, d_2, d_3)$ is a real function satisfying (2.6) and (2.7). We have the following result.

Proposition 5. Suppose that
$$
D_1 D_2 D_3 < P^{1/2-\epsilon}
$$
. We have

$$
\widetilde{\mathcal{H}}(D_1, D_2, D_3) \ll P^2 (\log P)^{-A}.
$$

We first explain that Proposition 3 can be deduced from Proposition 5. In order to prove

$$
\mathcal{H}(D) \ll P^2 (\log P)^{-A} \quad \text{for } D \le P^{1/2 - 5\varepsilon},
$$

we divide the underlying summation into two parts. Note that

$$
\mathcal{H}(D) = \sum_{\substack{d_1, d_2, d_3 \\ [d_1, d_2, d_3] \le D}} \beta(\mathbf{d}) \bigg(\mathcal{L}_{\mathbf{d}}(N) - \frac{\mathcal{N}_0(N) \Sigma_0(\mathbf{d}, N)}{d_1 d_2 d_3} \bigg)
$$
\n
$$
= \bigg(\sum_{\substack{d_1, d_2, d_3 \\ [d_1, d_2, d_3] \le P}} + \sum_{\substack{d_1, d_2, d_3 \\ [d_1, d_2, d_3] \le P}} \beta(\mathbf{d}) \bigg(\mathcal{L}_{\mathbf{d}}(N) - \frac{\mathcal{N}_0(N) \Sigma_0(\mathbf{d}, N)}{d_1 d_2 d_3} \bigg)
$$
\n
$$
=: \mathcal{H}_1(D) + \mathcal{H}_2(D).
$$

Since $\max_{i \le j} (d_i, d_j) \le P^{\varepsilon}$ and $[d_1, d_2, d_3] \le D$ together imply $d_1 d_2 d_3 \le P^{1/2-2\varepsilon}$, by the dyadic argument and Proposition 5, we can conclude

$$
\mathcal{H}_1(D) \ll P^2(\log P)^{-A}.
$$

Now we consider $\mathcal{H}_2(D)$ which is bounded by $\mathcal{H}'P^{\varepsilon/9}$, where

$$
\mathcal{H}' = \sum_{\substack{d_j \le D \ (1 \le j \le 3) \\ \max_{i < j} (d_i, d_j) \ge P^{\varepsilon}}} \left| \mathcal{L}_{\mathbf{d}}(N) - \frac{\mathcal{N}_0(N) \Sigma_0(\mathbf{d}, N)}{d_1 d_2 d_3} \right|.
$$

It suffices to verify $\mathcal{H}' \ll P^{2-\epsilon/5}$. By symmetry, the assertion is a consequence of

(7.1)
$$
\mathcal{H}'_1 := \sum_{\substack{d_j \le D \ (1 \le j \le 3) \\ (d_1, d_2) \ge P^{\varepsilon}}} \left| \frac{\mathcal{N}_0(N) \Sigma_0(\mathbf{d}, N)}{d_1 d_2 d_3} \right| \ll P^{2-\varepsilon/5}
$$

and

(7.2)
$$
\mathcal{H}'_2 := \sum_{\substack{d_j \leq D \ (1 \leq j \leq 3) \\ (d_1, d_2) \geq P^{\varepsilon}}} \mathcal{L}_{\mathbf{d}}(N) \ll P^{2-\varepsilon/5}.
$$

It has been pointed out in [9] that

$$
\Sigma_0(\mathbf{d}, N) \ll \tau^2(d_1^2)\tau^2(d_2^2)\tau^2(d_3^2) \log \log P \quad \text{and} \quad \mathcal{N}_0(N) \asymp \frac{P^2}{\log P}.
$$

Hence

$$
(7.3) \t\t \mathcal{H}'_1 \ll P^{2+\frac{\varepsilon}{10}} \sum_{\substack{d_j \le D \ (1 \le j \le 3) \\ (d_1, d_2) \ge P^{\varepsilon}}} \frac{1}{d_1 d_2 d_3} \ll P^{2+\frac{\varepsilon}{5}} \sum_{\substack{d_1 \le D, d_2 \le D \\ (d_1, d_2) \ge P^{\varepsilon}}} \frac{1}{d_1 d_2}.
$$

Note that $\omega(\mathbf{x}) \ll 1$, we have

$$
\mathcal{H}'_2 \ll \sum_{\substack{d_1 \le P, d_2 \le P \\ (d_1, d_2) \ge P^{\varepsilon}}} \sum_{\substack{x_1, x_2 \\ x_1, x_2 \ge \frac{Q}{2}}} \sum_{\substack{q, x_3, d_3 \\ q_1, x_2 \ge \frac{Q}{2} + x_1^2 + x_2^2 + x_3^2 = N}} 1.
$$

For fixed x_1, x_2 , the inner sum is bounded by $P^{\varepsilon/10}$. Hence

$$
(7.4) \t\t \mathcal{H}'_2 \ll P^{\varepsilon/10} \sum_{\substack{d_1 \le P, d_2 \le P \\ (d_1, d_2) \ge P^{\varepsilon}}}\sum_{\substack{x_1, x_2 \\ x_1 | x_1, d_2 | x_2}} 1 \ll P^{\varepsilon/10} \sum_{\substack{d_1 \le P, d_2 \le P \\ (d_1, d_2) \ge P^{\varepsilon}}} \frac{P^2}{d_1 d_2}.
$$

As an exercise, we have

$$
\sum_{\substack{d_1 \leq P, d_2 \leq P \\ (d_1, d_2) \geq P^{\varepsilon}}} \frac{1}{d_1 d_2} \leq \sum_{\delta \geq P^{\varepsilon}} \sum_{\substack{d'_1 \leq D/\delta \\ d'_2 \leq D/\delta}} \frac{1}{d'_1 d'_2 \delta^2} \ll P^{\varepsilon/10} \sum_{\delta \geq P^{\varepsilon}} \frac{1}{\delta^2} \ll P^{-\frac{9}{10}\varepsilon}.
$$

Now the estimates (7.1) and (7.2) follow from (7.3) and (7.4), respectively.

The remaining of this section is to show Proposition 5 by invoking Proposition 4. The proof follows the argument of Heath-Brown and Tolev closely. Let

$$
\mathcal{H}_1 = \sum_{\substack{d_i \le D_i \ (1 \le i \le 3) \\ (d_i, d_j) \le P^{\varepsilon} \ (1 \le i < j \le 3)}} \beta(\mathbf{d}) \mathcal{L}_{\mathbf{d}}(N).
$$

By applying Proposition 4, we see that

$$
\mathcal{H}_1 = \sum_{k \in \mathcal{A}_j} \omega(k) \sum_{\substack{d_i \le D_i \ (1 \le i \le 3) \\ (d_i, d_j) \le P^{\varepsilon} \ (1 \le i < j \le 3)}} \beta(\mathbf{d}) \Omega_{\mathbf{d}}(N - k^2) = \mathcal{H}_2 + O(P^{2-\varepsilon}),
$$

where

$$
\mathcal{H}_2 = \sum_{k \in \mathcal{A}_j} \omega(k) \sum_{\substack{d_i \le D_i \ (1 \le i \le 3) \\ (d_i, d_j) \le P^{\varepsilon} \ (1 \le i < j \le 3)}} \beta(\mathbf{d}) \mathcal{M}_{\mathbf{d}, Q}(N - k^2).
$$

Recalling the definition of $\mathcal{M}_{d, Q}(n)$, we know

$$
\mathcal{H}_2 = P \sum_{d_i \le D_i} \frac{\beta(\mathbf{d})}{(1 \le i \le 3)} \sum_{d_1 d_2 d_3} \sum_{q \le Q} q^{-3} \sum_{a(q)^*} S_{\mathbf{d}}(q, a)
$$

$$
\times \sum_{k \in \mathcal{A}_j} \omega(k) H\left(1 - \frac{k^2}{N}\right) e\left(\frac{a}{q}(k^2 - N)\right),
$$

where $\widetilde{\beta}(\mathbf{d})$ is $\beta(\mathbf{d})$ if $(d_i, d_j) \le P^{\varepsilon}$ $(1 \le i < j \le 3)$, and zero otherwise. Now partial summation gives

(7.5)
$$
\mathcal{H}_2 = -P \int \mathcal{B}(x) \left(\frac{d}{dx} \omega(x) H \left(1 - \frac{x^2}{N} \right) \right) dx,
$$

where

$$
\mathcal{B}(x) = \sum_{d_i \le D_i} \frac{\beta(\mathbf{d})}{(1 \le i \le 3)} \sum_{d_1 d_2 d_3} \sum_{q \le Q} q^{-3} \sum_{a(q)^*} S_{\mathbf{d}}(q, a) \mathcal{Z}(x)
$$

 \sim

and

$$
Z(x) = \sum_{\substack{k \le x \\ k \in A_j}} e\left(\frac{a}{q}(k^2 - N)\right).
$$

Let us write

$$
\mathcal{Z}_0(x) = \sum_{\substack{k \le x \\ k \in \mathcal{A}_j \\ (k,q)=1}} e\left(\frac{a}{q}(k^2 - N)\right).
$$

Then we have

$$
\mathcal{Z}(x) = \mathcal{Z}_0(x) + \sum_{\substack{k \le x \\ k \in \mathcal{A}_j \\ (k,q) > 1}} e\left(\frac{a}{q}(k^2 - N)\right),
$$

and thereby

$$
\mathcal{B}(x) = \mathcal{B}_0(x) + \mathbf{E}(x),
$$

 \sim

 \sim

where

$$
\mathcal{B}_0(x) = \sum_{d_i \le D_i} \frac{\beta(\mathbf{d})}{(1 \le i \le 3)} \sum_{d_1, d_2, d_3} \sum_{q \le Q} q^{-3} \sum_{a(q)^*} S_{\mathbf{d}}(q, a) \mathcal{Z}_0(x)
$$

and

$$
\mathbf{E}(x) = \sum_{d_i \le D_i} \sum_{(1 \le i \le 3)} \frac{\beta(\mathbf{d})}{d_1 d_2 d_3} \sum_{q \le Q} q^{-3} \sum_{a(q)^*} S_{\mathbf{d}}(q, a) \sum_{\substack{k \le x \\ k \in \mathcal{A}_j \\ (k, q) > 1}} e\left(\frac{a}{q} (k^2 - N)\right).
$$

If $(k, q) > 1$ and $k \in \mathcal{A}_j$, then $(k, q) \ge P^{1/16}$. So we have

$$
\mathbf{E}(x) = \sum_{h \ge P^{1/16}} \sum_{d_i \le D_i} \sum_{\substack{(1 \le i \le 3)}} \frac{\beta(\mathbf{d})}{d_1 d_2 d_3} \sum_{\substack{q \le Q/h}} \sum_{\substack{k \le x/h \\ kh \in \mathcal{A}_j \\ (k,q)=1}} q^{-3} h^{-3}
$$

$$
\times \sum_{\substack{a(hq)^*}} S_{\mathbf{d}}(hq, a) e\left(\frac{a}{hq}(k^2 h^2 - N)\right).
$$

For the inner sum above, we have the bound

$$
\sum_{a(q)^*} S_{\mathbf{d}}(q, a) e\left(-\frac{a}{q}n\right) \ll (n, q)(q, d_1^2)^{1/2} (q, d_2^2)^{1/2} (q, d_3^2)^{1/2} q^2.
$$

Then we get

$$
\mathbf{E}(x) \ll P^{\varepsilon} \sum_{h \ge P^{1/16}} \sum_{q \le Q/h} q^{-1} h^{-1} \sum_{k \le x/h} (N - k^2 h^2, q h).
$$

We finally find that

$$
\mathbf{E}(x) \ll P^{1-1/16+\varepsilon}
$$

:

For $(m, q) = 1$, we introduce the notation

$$
\Delta_j(x; q, m) = \sum_{\substack{k \le x \\ k \in \mathcal{A}_j \\ k \equiv m \pmod{q}}} 1 - \frac{1}{\phi(q)} \Lambda_j(x; q),
$$

where

$$
\Lambda_j(x;q) = \sum_{\substack{k \le x \\ k \in \mathcal{A}_j \\ (k,q)=1}} 1.
$$

Then we have

$$
\mathcal{Z}_0(x) = \frac{1}{\phi(q)} e\left(\frac{-aN}{q}\right) T(q,a) \Lambda_j(x;q) + \sum_{m(q)^*} e\left(\frac{a(m^2 - N)}{q}\right) \Delta_j(x;q,m).
$$

Therefore

$$
\mathcal{B}_0(x) = \widetilde{\mathcal{B}}_0(x) + \mathcal{C}(x),
$$

where

$$
\widetilde{\mathcal{B}}_0(x) = \sum_{d_i \le D_i} \frac{\beta(\mathbf{d})}{(1 \le i \le 3)} \frac{\beta(\mathbf{d})}{d_1 d_2 d_3} \sum_{q \le Q} h_{\mathbf{d}}(q) \Lambda_j(x; q)
$$

and

$$
\mathcal{C}(x) = \sum_{d_i \leq D_i} \frac{\widetilde{\beta}(\mathbf{d})}{d_1 d_2 d_3} \sum_{q \leq Q} q^{-3} \sum_{a(q)^*} S_{\mathbf{d}}(q, a) \sum_{m(q)^*} e\left(\frac{a(m^2 - N)}{q}\right) \Delta_j(x; q, m).
$$

Define

$$
L = \sum_{q \le Q} \sum_{m(q)^*} \Delta_j(x; q, m)^2
$$

Brought to you by | University of Notre Dame Authenticated Download Date | 8/2/18 2:22 PM and

$$
M = \sum_{q \le Q} \sum_{m(q)^*} \Gamma(q, m)^2,
$$

 \sim

where

$$
\Gamma(q,m) = q^{-3} \sum_{d_i \le D_i \ (1 \le i \le 3)} \frac{\beta(\mathbf{d})}{d_1 d_2 d_3} \sum_{a(q)^*} S_{\mathbf{d}}(q,a) e\left(\frac{a}{q}(m^2 - N)\right).
$$

It has been proved in [9] that $M \ll (\log P)^C$ for some absolute constant $C > 0$ (see [9, (274)]). The Generalized Barban–Davenport–Halberstam Theorem states that

 $L \ll P^2(\log P)^{-A}.$

Observing that

$$
\mathcal{C}(x) = \sum_{q \le Q} \sum_{m(q)^*} \Delta_j(x; q, m) \Gamma(q, m),
$$

one can conclude by Cauchy's inequality

$$
\mathcal{C}(x) \ll P(\log P)^{-A}.
$$

Let

$$
A(x) = \sum_{\substack{k \le x \\ k \in A_j}} 1.
$$

Note that $\Lambda_j(x; q) = A(x) + O(P^{1-1/16+\epsilon})$ and

$$
\sum_{q \le Q} |h_{\mathbf{d}}(q)| \ll \tau^2(d_1) \tau^2(d_2) \tau^2(d_3) \log \log P.
$$

Then we have

$$
\widetilde{\mathcal{B}}_0(x) = \mathcal{B}_0 A(x) + O(P^{1-1/16+\varepsilon}),
$$

where

$$
\mathcal{B}_0 = \sum_{d_i \le D_i \ (1 \le i \le 3)} \frac{\beta(\mathbf{d})}{d_1 d_2 d_3} \sum_{q \le Q} h_{\mathbf{d}}(q).
$$

It is not hard to see that

$$
\mathcal{B}_0 = \mathcal{B}_1 + O(P^{-1/2 + \varepsilon}),
$$

where

$$
\mathcal{B}_1 = \sum_{d_i \le D_i} \frac{\widetilde{\beta}(\mathbf{d})}{(1 \le i \le 3)} \sum_{d_1 d_2 d_3}^{\infty} \sum_{q=1}^{\infty} h_{\mathbf{d}}(q).
$$

Therefore

(7.6)
$$
\mathcal{B}(x) = \mathcal{B}_1 A(x) + O(P(\log P)^{-A}).
$$

By the Prime Number Theorem, we have

$$
A(x) = \int_2^x \frac{C_j(t)}{\log t} dt + O(P(\log P)^{-A}).
$$

Now combining (7.5) and (7.6), we arrive at

$$
\mathcal{H}_2 = P \mathcal{B}_1 \int \omega(x) H\left(1 - \frac{x^2}{N}\right) \frac{C_j(x)}{\log x} dx + O(P^2(\log P)^{-A}).
$$

The proof of Proposition 5 is completed and therefore Proposition 3 is also established.

8. The review of the three-dimensional sieve

In this section, we recall the Diamond–Halberstam–Richert sieves. One may refer to [7] for the details. We shall focus on the case that the sieve dimension $\kappa = 3$. Let σ_{κ} be the continuous solution of the differential delay problem

$$
u^{\kappa} \sigma_{\kappa}(u) = (2e^{\gamma})^{\kappa} (\Gamma(\kappa + 1))^{-1}, \quad 0 < u \le 2,
$$
\n
$$
(u^{\kappa} \sigma_{\kappa}(u))' = -\kappa u^{-\kappa - 1} \sigma_{\kappa}(u - 2), \quad u > 2,
$$

where γ is Euler's constant and Γ is Euler's gamma function.

Let $F_k(u)$ and $f_k(u)$ be the continuous solutions of the simultaneous differential delay system

(8.1)

$$
\begin{cases}\nF_{\kappa}(u) = \frac{1}{\sigma_{\kappa}(u)}, & 0 < u \le \alpha_{\kappa}, \\
f_{\kappa}(u) = 0, & 0 \le u \le \beta_{\kappa}, \\
(u^{\kappa} F_{\kappa}(u))' = \kappa u^{\kappa - 1} f_{\kappa}(u - 1), & u > \alpha_{\kappa}, \\
(u^{\kappa} f_{\kappa}(u))' = \kappa u^{\kappa - 1} F_{\kappa}(u - 1), & u > \beta_{\kappa},\n\end{cases}
$$

where α_{κ} and β_{κ} are real numbers such that

$$
3 < \beta_{\kappa} + 1 < \alpha_{\kappa}.
$$

We note that

- (i) $F_k(u)$ decreases monotonically toward 1 as $u \to \infty$,
- (ii) $f_k(u)$ increases monotonically toward 1 as $u \to \infty$.

Suppose that $\{a_n\}$ is a (finite) sequence of non-negative real numbers. Then we introduce

$$
\mathcal{A}(d) = \sum_{n \equiv 0 \pmod{d}} a_n.
$$

It is expected that $\frac{\Omega(t)}{t}$ X is a good approximation to $\mathcal{A}(t)$, where $\Omega(t)$ is a multiplicative function satisfying

$$
(8.2) \t\t 0 \le \Omega(p) < \min\{p, c\}
$$

for some constant c , and

(8.3)
$$
\prod_{w_1 \le p < w} \left(1 - \frac{\Omega(p)}{p}\right)^{-1} \le \left(\frac{\log w}{\log w_1}\right)^3 \left(1 + \frac{c_1}{\log w_1}\right), \quad 2 \le w_1 < w,
$$

for some constant $c_1 > 0$. Suppose that there exists a constant $c_2 \geq 2$ such that

(8.4)
$$
\sum_{t \leq D} \mu^2(t) \tau^2(t) \left| \mathcal{A}(t) - \frac{\Omega(t)}{t} X \right| \leq c_2 \frac{X}{(\log X)^4}.
$$

Let $\Pi(z) = \prod_{p \leq z} p$ and define

$$
V(x) = \prod_{p \le x} \left(1 - \frac{\Omega(p)}{p} \right).
$$

Then one has

(8.5)
$$
\sum_{(n,\Pi(z))=1} a_n \leq XV(z) \bigg(F_{\kappa}(s) + O\bigg(\frac{(\log \log X)^2}{(\log X)^{1/8}} \bigg) \bigg)
$$

and

(8.6)
$$
\sum_{(n,\Pi(z))=1} a_n \geq XV(z) \bigg(f_{\kappa}(s) + O\bigg(\frac{(\log \log X)^2}{(\log X)^{1/8}} \bigg) \bigg),
$$

where $s = \log D / \log z$.

By (8.1), for $s > \beta_{\kappa}$ we have

$$
s^{\kappa} f_{\kappa}(s) = \int_{\beta_{\kappa}}^{s} \kappa u^{\kappa - 1} F_{\kappa}(u - 1) du > F_{\kappa}(s) \int_{\beta_{\kappa}}^{s} \kappa u^{\kappa - 1} du = F_{\kappa}(s) (s^{\kappa} - \beta^{\kappa}_{\kappa}).
$$

Therefore one has

(8.7)
$$
\frac{f_{\kappa}(s)}{F_{\kappa}(s)} > 1 - \left(\frac{\beta_{\kappa}}{s}\right)^{\kappa}.
$$

9. Applications of the switching principle

Let

$$
\mathcal{A}(t) = \mathcal{A}(t, N) := \mathcal{A}^{(j)}(t, N) = \sum_{\substack{q^2 + x_1^2 + x_2^2 + x_3^2 = N \\ q \in \mathcal{A}_j \\ t \mid x_1 x_2 x_3}} \omega(q)\omega(\mathbf{x}).
$$

Note that the function

$$
g(t) = \mu(t) \sum_{\substack{\mathbf{d} \\ [d_1, d_2, d_3] = t \\ d_j \, | \, x_j \, (1 \le j \le 3)}} \mu(d_1) \mu(d_2) \mu(d_3)
$$

is a multiplicative function of t. If t is square-free and t | $x_1x_2x_3$, then $g(t) = 1$, and $g(t) = 0$ otherwise. Hence for t square-free, we have

$$
\mathcal{A}(t) = \sum_{\substack{q^2 + x_1^2 + x_2^2 + x_3^2 = N \\ q \in \mathcal{A}_j \\ t \mid x_1 x_2 x_3}} \omega(q) \omega(\mathbf{x}) \mu(t) \sum_{\substack{\mathbf{d} \\ [d_1, d_2, d_3] = t \\ d_j \mid x_j \ (1 \le j \le 3)}} \mu(d_1) \mu(d_2) \mu(d_3).
$$

By interchanging the summations, we get

(9.1)
$$
\mathcal{A}(t) = \mu(t) \sum_{\substack{\mathbf{d} \\ [d_1, d_2, d_3] = t}} \mu(d_1) \mu(d_2) \mu(d_3) \mathcal{L}_{\mathbf{d}}(N),
$$

where $\mathcal{L}_{d}(N)$ is defined in (2.4). The expected main term for $\mathcal{A}(t)$ is

(9.2)
$$
\mathcal{M}_t = \mu(t) \sum_{\substack{\mathbf{d} \\ [d_1, d_2, d_3] = t}} \mu(d_1) \mu(d_2) \mu(d_3) \frac{\Sigma_0(\mathbf{d}, N) \mathcal{N}_0(N)}{d_1 d_2 d_3},
$$

where $\Sigma_0(\mathbf{d}, N)$ and $\mathcal{N}_0(N)$ are given in (2.2) and (2.5) respectively.

Let $X = \Sigma_0(e, N) \mathcal{N}_0(N)$ with $e = (1, 1, 1)$. We point out that for $N \equiv 4 \pmod{24}$ (cf. [9, (311)]),

$$
1 \ll \Sigma_0(\mathbf{e}, N) \ll \log \log N.
$$

Therefore we can define

$$
\Omega(t) = t\mu(t) \sum_{\substack{\mathbf{d} \\ [d_1, d_2, d_3] = t}} \mu(d_1)\mu(d_2)\mu(d_3) \frac{\Sigma_0(\mathbf{d}, N)}{d_1 d_2 d_3 \Sigma_0(\mathbf{e}, N)}.
$$

Then we see that

$$
\mathcal{M}_t = \frac{\Omega(t)}{t} X.
$$

For $p > 2$, we define

$$
h_0(p) = \begin{cases} \frac{1}{p} & \text{if } p \mid N, \\ \frac{-1}{p(p-1)}(1 + \frac{-N}{p}) & \text{if } p \nmid N, \end{cases}
$$

\n
$$
h_1(p) = \begin{cases} \frac{-1}{p} \left(\frac{-1}{p}\right) & \text{if } p \mid N, \\ \frac{1}{p-1} \left(\frac{-N}{p}\right) + \frac{1}{p} \left(\frac{-1}{p}\right) & \text{if } p \nmid N, \end{cases}
$$

\n
$$
h_2(p) = \begin{cases} \frac{-1}{p} & \text{if } p \mid N, \\ \frac{-1}{p-1} \left(\frac{-1}{p}\right) + \left(\frac{N}{p}\right) & \text{if } p \nmid N, \end{cases}
$$

\n
$$
h_3(p) = \begin{cases} -1 & \text{if } p \mid N, \\ \frac{1}{p-1} \left(p\left(\frac{N}{p}\right) + 1\right) & \text{if } p \nmid N. \end{cases}
$$

The function $\Omega(t)$ is multiplicative with

$$
\Omega(p) = \frac{3(1 + h_1(p))}{1 + h_0(p)} - \frac{3(1 + h_2(p))}{p(1 + h_0(p))} + \frac{1 + h_3(p)}{p^2(1 + h_0(p))}
$$

for $p > 2$ and $\Omega(2) = 0$. One can easily show that

$$
0 \leq \Omega(p) < \min\{p, 8\}
$$

and

$$
\Omega(p) = 3 + O\bigg(\frac{1}{p}\bigg).
$$

Hence (8.2) and (8.3) are established. Now we turn to (8.4). We have

$$
E(D) := \sum_{t \le D} \mu^2(t) \tau^2(t) \left| \mathcal{A}(t) - \frac{\Omega(t)}{t} X \right|
$$

=
$$
\sum_{t \le D} \mu^2(t) \tau^2(t) \xi(t, N) \left(\mathcal{A}(t) - \frac{\Omega(t)}{t} X \right),
$$

where

$$
\xi(t,N) = \begin{cases} |\mathcal{A}(t) - \frac{\Omega(t)}{t} X| (\mathcal{A}(t) - \frac{\Omega(t)}{t} X)^{-1} & \text{if } \mathcal{A}(t) - \frac{\Omega(t)}{t} X \text{ is non-zero,} \\ 0 & \text{otherwise.} \end{cases}
$$

Recalling (9.1) , (9.2) and (9.3) , we have

(9.4)
$$
E(D) = \sum_{\substack{d_1, d_2, d_3\\[d_1, d_2, d_3] \le D}} \beta(d_1, d_2, d_3) \left(\mathcal{L}_{\mathbf{d}}(N) - \frac{\Sigma_0(\mathbf{d}, N) \mathcal{N}_0(N)}{d_1 d_2 d_3} \right),
$$

where

$$
\beta(d_1, d_2, d_3) = \mu(d_1)\mu(d_2)\mu(d_3)\mu([d_1, d_2, d_3])\tau^2([d_1, d_2, d_3])\xi([d_1, d_2, d_3], N).
$$

Obviously,

$$
\beta(d_1, d_2, d_3) \ll \prod_{j=1}^{3} \tau^2(d_j).
$$

Invoking Proposition 3, we see that (8.4) holds true with $D = P^{1/2-\epsilon}$. Therefore the inequalities (8.5) and (8.6) hold for the sequence

$$
a_n := a_n^{(j)} = \sum_{\substack{q^2 + x_1^2 + x_2^2 + x_3^2 = N \\ q \in \mathcal{A}_j \\ x_1 x_2 x_3 = n}} \omega(q) \omega(\mathbf{x}).
$$

Lemma 16. Let $c_1(t) = 1$ or $c_1(t) = 0$ according to $t \ge 1$ or $t < 1$. We define $c_j(t)$ *inductively by*

$$
c_j(t) = \int_j^{\max(j,t)} \frac{c_{j-1}(x-1)}{x-1} dx.
$$

Then for $1 \leq j \leq 15$ *, one has*

$$
\frac{N}{\log N} \ll \mathcal{N}_0^j(N) \ll \frac{N}{\log N}
$$

and

$$
\mathcal{N}_0^j(N) = \left(c_j(16) + O\left(\frac{1}{\log N}\right)\right) \mathcal{N}_0^1(N).
$$

Proof. In view of [2, (2.16)], we have

$$
C_j(x) = c_j(16) + O\left(\frac{1}{\log N}\right) \quad \text{for } \frac{P}{2} < x < P.
$$

Hence

$$
\mathcal{N}_0^j(N) - c_j(16)\mathcal{N}_0^1(N) \ll \frac{N}{\log^2 N}.
$$

We get the desired results by observing that

$$
\frac{N}{\log N} \ll \mathcal{N}_0^1(N) \ll \frac{N}{\log N}.
$$

Remark. We record some numerical values:

 $c_2(16) > 2.70805$, $c_3(16) > 2.912112$, $c_4(16) > 1.663428$, $c_5(16) > 0.563668$.

Proof of Theorem 1.1*.* Our objective is to prove

$$
R(N) := \sum_{\substack{p^2 + x_1^2 + x_2^2 + x_3^2 = N \\ x_1, x_2, x_3 \in \bigcup_{j=1}^5 \mathcal{A}_j}} \omega(p)\omega(\mathbf{x}) > 0.
$$

Observe that

$$
\sum_{p \in A_1} \sum_{x_1, x_2, x_3 \in \bigcup_{j=1}^5 A_j} - \sum_{p \in A_1} \sum_{\substack{p \in A_1 \\ x_1 \in \bigcup_{j=6}^5 A_j \\ x_2, x_3 \in \bigcup_{j=1}^5 A_j \\ x_3 \in \bigcup_{j=1}^5 A_j}} - \sum_{\substack{p \in A_1 \\ x_1 \in \bigcup_{j=6}^5 A_j \\ x_2, x_3 \in \bigcup_{j=1}^5 A_j \\ x_3 \in \bigcup_{j=1}^5 A_j \\ x_4 \in \bigcup_{j=1}^5 A_j \\ x_1, x_2, x_3 \in \bigcup_{j=1}^5 A_j} - \sum_{\substack{q \in \bigcup_{j=1}^5 A_j \\ q \in \bigcup_{j=1}^5 A_j \\ x_1 \in \bigcup_{j=6}^5 A_j \\ x_1 \in \bigcup_{j=6}^5 A_j \\ x_1 \in \bigcup_{j=6}^5 A_j \\ x_2 \in \bigcup_{j=6}^5 A_j \\ x_2 \in \bigcup_{j=6}^5 A_j \\ x_3 \in \bigcup_{j=1}^5 A_j \\ x_4 \in \bigcup_{j=1}^5 A_j \\ x_1, x_2, x_3 \in \bigcup_{j=1}^5 A_j \\ x_1, x_3 \in \bigcup_{j=1}^5 A_j \\ x_1, x_2 \in \bigcup_{j=1}^5 A_j \\ x_1, x_3 \in \bigcup_{j=1}^5 A_j \\ x_1, x_2 \in \bigcup_{j=1}^5 A_j
$$

By switching the roles of q and x_j , we obtain

$$
R(N) \geq \sum_{\substack{p^2 + x_1^2 + x_2^2 + x_3^2 = N \\ x_1, x_2, x_3 \in \bigcup_{j=1}^{15} \mathcal{A}_j}} \omega(p) \omega(\mathbf{x}) - 3 \sum_{\substack{q^2 + x_1^2 + x_2^2 + x_3^2 = N \\ q \in \bigcup_{j=6}^{15} \mathcal{A}_j \\ x_1, x_2, x_3 \in \bigcup_{j=1}^{15} \mathcal{A}_j}} \omega(q) \omega(\mathbf{x}).
$$

In view of the three-dimensional sieve, we have

$$
\sum_{\substack{p^2 + x_1^2 + x_2^2 + x_3^2 = N \\ x_1, x_2, x_3 \in \bigcup_{j=1}^{15} A_j}} \omega(p)\omega(\mathbf{x}) = \sum_{\substack{(n, \Pi(z)) = 1 \\ (n, \Pi(z)) = 1}} \sum_{\substack{p^2 + x_1^2 + x_2^2 + x_3^2 = N \\ x_1 x_2 x_3 = n}} \omega(p)\omega(\mathbf{x})
$$
\n
$$
\ge (f_3(8 - \varepsilon) - \varepsilon) \Sigma_0(\mathbf{e}, N) \mathcal{N}_0^1(N) V(z),
$$

where $z = P^{1/16}$. Similarly,

$$
\sum_{\substack{q^2+x_1^2+x_2^2+x_3^2=N\\ q\in \bigcup_{j=6}^{15} A_j}} \omega(q)\omega(\mathbf{x}) = \sum_{j=6}^{15} \sum_{\substack{(n,\Pi(z))=1\\ (n,\Pi(z))=1}} \sum_{\substack{q^2+x_1^2+x_2^2+x_3^2=N\\ q\in A_j\\ x_1x_2x_3=n}} \omega(q)\omega(\mathbf{x})
$$
\n
$$
\leq (F_3(8-\varepsilon)+\varepsilon)\sum_{0}(\mathbf{e}, N) \sum_{j=6}^{15} \mathcal{N}_0^j(N)V(z).
$$

By Lemma 16, we obtain

$$
\sum_{\substack{q^2+x_1^2+x_2^2+x_3^2=N\\ q\in \bigcup_{j=6}^{15}\mathcal{A}_j}} \omega(q)\omega(\mathbf{x}) \le \left(F_3(8-\varepsilon)\sum_{j=6}^{15}c_j(16)+\varepsilon\right)\Sigma_0(\mathbf{e},N)\mathcal{N}_0^1(N)V(z).
$$

:

Therefore

$$
R(N) \ge \left(f_3\left(\frac{16}{2}\right) - 3F_3\left(\frac{16}{2}\right) \sum_{j=6}^{15} c_j (16) - \varepsilon \right) \Sigma_0(\mathbf{e}, N) \mathcal{N}_0^1(N) V(z)
$$

=
$$
\left(\frac{f_3(8)}{3F_3(8)} - \sum_{j=6}^{15} c_j (16) - \varepsilon \right) 3F_3(8) \Sigma_0(\mathbf{e}, N) \mathcal{N}_0^1(N) V(z)
$$

=
$$
(C_0 - \varepsilon) 3F_3(8) \Sigma_0(\mathbf{e}, N) \mathcal{N}_0^1(N) V(z),
$$

where

$$
C_0 = \frac{f_3(8)}{3F_3(8)} - \sum_{j=6}^{15} c_j(16).
$$

By (8.7) , we have

$$
\frac{f_3(8)}{F_3(8)} > 1 - \left(\frac{\beta_3}{8}\right)^3,
$$

where $\beta_3 \leq 6.640859$. Thus

$$
C_0 > \frac{1}{3} \left(1 - \left(\frac{\beta_3}{8} \right)^3 \right) - \sum_{j=6}^{15} c_j (16).
$$

Now numerical computations reveal that $C_0 > 0.003$. Thus Theorem 1.1 is established. \Box

One can do numerical computations in the following way. We have

$$
C_0 > \frac{1}{3} \left(1 - \left(\frac{\beta_3}{8} \right)^3 \right) + \sum_{j=1}^5 c_j (16) - \sum_{j=1}^{15} c_j (16).
$$

Brüdern and Kawada pointed out that as a consequence of linear sieve, one has (see [2, (6.35)])

$$
\sum_{j=1}^{15} c_j (16) \le 16e^{-\gamma} F_1(16) \le 16e^{-\gamma} (1+10^{-9}).
$$

Therefore,

$$
C_0 > \frac{1}{3} \left(1 - \left(\frac{\beta_3}{8} \right)^3 \right) + \sum_{j=1}^5 c_j (16) - 16e^{-\gamma} (1 + 10^{-9}).
$$

Then we actually need the numerical values of c_j (16) for $1 \le j \le 5$.

Proof of Theorem 1.2*.* The proof is as same as Theorem 1.1 except that we consider

$$
R'(N) := \sum_{\substack{q^2 + x_1^2 + x_2^2 + x_3^2 = N \\ q, x_1, x_2, x_3 \in \bigcup_{j=1}^4 \mathcal{A}_j}} \omega(q) \omega(\mathbf{x}).
$$

In view of the switching principle and the three-dimensional sieve, the lower bound for $R'(N)$ is

$$
R'(N) \ge \left(f_3(8) \sum_{j=1}^4 c_j (16) - 3F_3(8) \sum_{j=5}^{15} c_j (16) - \varepsilon \right) \Sigma_0(\mathbf{e}, N) \mathcal{N}_0^1(N) V(z)
$$

=
$$
\left(\frac{f_3(8)}{3F_3(8)} \sum_{j=1}^4 c_j (16) - \sum_{j=5}^{15} c_j (16) - \varepsilon \right) 3F_3(8) \Sigma_0(\mathbf{e}, N) \mathcal{N}_0^1(N) V(z)
$$

=
$$
(C'_0 - \varepsilon) 3F_3(8) \Sigma_0(\mathbf{e}, N) \mathcal{N}_0^1(N) V(z),
$$

where

$$
C_0' = \frac{f_3(8)}{3F_3(8)} \sum_{j=1}^{4} c_j (16) - \sum_{j=5}^{15} c_j (16).
$$

Similarly, we have

$$
C_0' > \frac{1}{3} \left(1 - \left(\frac{\beta_3}{8} \right)^3 \right) \sum_{j=1}^4 c_j (16) + \sum_{j=1}^4 c_j (16) - 16 e^{-\gamma} (1 + 10^{-9}).
$$

Again a numerical computation reveals that $C'_0 > 0$. We point out that we gain P_4 instead of P_5 due to the constant $\sum_{j=1}^{4} c_j (16)$ in place of 1. This completes the proof of Theorem 1.2.

Acknowledgement. The authors wish to thank Professors Jörg Brüdern and Maosheng Xiong for their helpful comments. The authors also wish to thank Dr. Yuk-Kam Lau for his many helpful discussions.
