ABSTRACT (250 words)

Background: Fetal akinesia and arthrogryposis are clinically and genetically heterogeneous and have traditionally been refractive to genetic diagnosis. The widespread availability of affordable genome-wide sequencing has facilitated accurate genetic diagnosis and gene discovery in these conditions.

Methods: We performed next generation sequencing (NGS) in 190 probands with a diagnosis of arthrogryposis multiplex congenita, distal arthrogryposis, fetal akinesia deformation sequence or multiple pterygium syndrome. This sequencing was a combination of bespoke neurogenetic disease gene panels and whole exome sequencing. Only Class 4 and 5 variants were reported, except for two cases where the identified variants of unknown significance (VUS) are most likely to be causative for the observed phenotype. Co-segregation studies and confirmation of variants identified by NGS were performed where possible. Functional genomics was performed as required.

Results: Of the 190 probands, 81 received an accurate genetic diagnosis. All except two of these cases harboured Class 4 and/or 5 variants based on ACMG guidelines. We identified phenotypic expansions associated with *CACNA1S, CHRNB1, GMPPB* and *STAC3*. We describe a total of 50 novel variants, including a novel missense variant in the recently identified gene for arthrogryposis with brain malformations – *SMPD4*.

Conclusions: Comprehensive gene panels give a diagnosis for a substantial proportion (42%) of fetal akinesia and arthrogryposis cases, even in an unselected cohort. Recently identified genes account for a relatively large proportion, 32%, of the diagnoses. Diagnostic-research collaboration was critical to the diagnosis and variant interpretation in many cases, facilitated genotype-phenotype expansions and reclassified VUS through functional genomics.

Keywords: fetal akinesia, arthrogryposis, next generation sequencing, genotype-phenotype, functional genomics, *SMPD4, STAC3, CHRNB1, GLDN, GMPPB*

INTRODUCTION

Fetal akinesia or hypokinesia can result in a range of clinical presentations, including; fetal akinesia deformation sequence (FADS),[1] arthrogryposis multiplex *congenita* (AMC), distal arthrogryposis (DA),[2] lethal congenital contracture syndromes (LCCS), and multiple pterygium syndrome (MPS). Many of these conditions have overlapping features including: joint contractures, pterygia, fetal hydrops, lung hypoplasia and dysmorphic features. While fetal akinesia is frequently diagnosed *in utero*, following abnormal indications on routine ultrasounds and/or maternal reporting of reduced fetal movements, many cases are not detected until birth, when they present with contractures and associated complications.[3] For the purposes of this manuscript, the term fetal akinesia is used as an umbrella description for all entities described above.

Fetal akinesia can arise from gene defects or maternal/external factors. In recent years the contribution of variants in genes that encode critical neuromuscular system proteins has become increasingly recognised as a cause of fetal akinesia. Variants in >70 of these genes are now known to cause fetal akinesia.[4-7]

As was foreshadowed for rare diseases,[8] many novel phenotypes have been attributed to variants in known disease genes – this is also true for the fetal akinesias. In particular, bi-allelic null variants in genes previously associated with autosomal dominant neuromuscular disease have now been associated with fetal akinesia, e.g. recessive *CACNA1S*,[9] *DNM2*,[10] *RYR1*,[11] *SCN4A*,[12] *TOR1A*,[13] and *TTN*[14] disease.

In this study we present our findings from massively parallel sequencing in a cohort of 190 probands presenting with fetal akinesia. We achieved an accurate genetic diagnosis in 81 of these cases, identified two then novel disease genes,[15,16] described 50 novel variants and extended the phenotypes associated with known neuromuscular disease genes.

METHODS

Cohort details

This cohort includes 190 probands with a clinical diagnosis of arthrogryposis multiplex *congenita*, distal arthrogryposis, fetal akinesia deformation sequence, multiple pterygium syndrome (Escobar-variant or lethal) or Schwartz Jampel Syndrome [n=2]. Additional features included CNS involvement (lissencephaly [n=3], polymicrogyria [n=5]), neuropathy (n=2), and congenital myopathy (n=5).

Recruitment into this project was via two arms: (1) cases submitted for diagnostic testing via the PathWest neurogenetic gene panels (some of which were then enrolled in research testing, if no genetic diagnosis was provided in the diagnostic setting), and (2) cases consented for research that underwent testing via the PathWest neurogenetic gene panels and/or whole exome sequencing (WES). Of the 190 patients, 146 underwent diagnostic testing, 16 were studied in both the diagnostic and research setting, and 28 were analysed in the research setting only. Of the 190 probands, all except 15 were from Australia/NZ. These 15 cases were part of the research recruitment arm of this study.

Testing was performed via the PathWest neurogenetic gene panel alone for 150 probands. Combined panel and WES was performed in 29 probands whilst in the remaining 11 probands only WES was performed. The number of probands sequenced on each version of the panel were: 33 (v1), 37 (v2) and 109 (v3).

NGS: Neurogenetic disease gene panel sequencing, mapping and analysis

Next generation sequencing was performed on custom-designed neurogenetic disease gene panels (versions 1-3). Details of versions 1 and 2 of the panel are outlined in Beecroft *et al*.[17] For design of the third iteration of the panel, the genes were split into two panels: a muscle disease gene panel (v3 muscle) and a neurogenic disease gene panel (v3 neuro), with some overlap as appropriate. Sequencing for v3 was performed using Illumina Nextera Rapid Capture Custom Enrichment Kit and sequenced on an Illumina Benchtop Sequencer. Average coverage was 309 fold for versions 1 and 2 of the panel and 350-fold for v3. The minimum accepted coverage cutoffs were as follows; average coverage> 150-fold (v1-3), and 92% (v1-2) or 95% (v3) of te target regions covered to >20x. Details of the genes included in each iteration of the panel are included in

Supplementary Table 1. During the iterative process, panels were spiked with probes to known low-coverage regions to facilitate deeper sequencing.[17] Base calling, mapping, and variant calling were performed using Torrent Suite 3.6.2 or 4.2 with germline high stringency settings (GRCh37), with default values as outlined at: https://github.com/iontorrent/TS/blob/master/plugin/variantCaller/pluginMedia/parameter_sets/4_4/ampliseqexome_germline_highstringency_p1_parameters.json. For v3 of the panel all mapping and calling was done by the BWA Enrichment App v2.1.2 on the Illumina Basespace Sequence Hub using our custom bed files.

In the diagnostic setting, Cartagenia BenchLab/Alissa software (Agilent Technologies) was used for annotation and analysis. Bioinformatic filters were used as a first pass to restrict analysis to a sub-panel of genes associated with each clinical phenotype. If no pathogenic variant was identified, rare coding variants across all genes on the panel were analysed. Variants with a minor allele frequency of >2% were filtered from the analysis. The diagnostic laboratory adopted the American College of Medical Genetics (ACMG) guidelines to classify variants when they became available in 2015.[18]

The research team was able to interpret variants on a research-only basis in Cartagenia/Alissa software, without analysis restricted to sub-panels of genes. If a likely reportable variant was found (Class 4 or 5), interpretation was referred to PathWest for validation in the Australian National Association of Testing Authorities (NATA) accredited laboratory or, in the case of overseas samples, the research findings were reported to the consenting clinician for confirmation by their corresponding diagnostic genomics laboratory. Class 3 variants were followed up with appropriate literature searchs, consultation with international experts, and functional genomics where possible.

This project was approved by the Human Research Ethics Committee of the University of Western Australia (approval number RA/4/20/1008) and participants provided informed consent.

NGS - Whole exome sequencing, mapping and analysis

Ampliseq whole exome sequencing was performed by the Lotterywest State Biomedical Facility Genomics (LSBFG) as previously described.[5,16] Illumina whole exome sequencing

(WES) was performed at either the Australian Genomics Research Facility (AGRF) or the Center for Mendelian Genomics (CMG; The Broad). For AGRF and LSBFG exomes, processing from FASTQ to VCF was performed as per the GATK best practice guidelines version 3.6 (https://software.broadinstitute.org/gatk). VCFs and pedigree information were compiled in a GEMINI database for variant annotation and querying.[19] Variant annotation was performed as described previously[20] with additional filtering: variants with a minor allele frequency of >1%, or which were seen in the homozygous state in ExAC and gnomAD were excluded from downstream analysis. Variants observed >10 times within the GEMINI database were also removed, which removed many sequencing artefacts. Scripts were used to extract variants compatible with the presumed modes of inheritance (autosomal recessive and *de novo* dominant).

CMG exomes were analysed in seqr (https://seqr.broadinstitute.org). CNV detection was performed using The Broad's GATK gCNV calling pipeline, as outlined (https://github.com/broadinstitute/gatk-protected/blob/master/docs/CNVs/CNV-methods.pdf).

Variant confirmation and interpretation

Bi-directional Sanger sequencing was used to confirm missense and indel variants and to determine co-segregation with disease where parental and sibling DNAs were available. CNVs were confirmed using multiplex ligation-dependent probe amplification (MLPA).

In the case of apparent *de novo* variants, samples from the parents and affected individual were sequenced across a panel of microsatellites to check that the samples were compatible with the provided family structure (i.e. to confirm paternity and rule out the possibility of sample mix-ups).

For missense variants, likely pathogenicity was explored using *in silico* tools including: CADD,[21], MuPro,[22] MutationAssessor, MutationTaster, PolyPhen-2[23] PROVEAN[24] and SIFT.[25]

cDNA studies

For muscle cDNA studies, 10 µm frozen sections were cut on a Leica ultramicrotome and collected into a pre-chilled microfuge tube. RNA extraction was performed using the RNeasy (fibrous tissue) kit (QIAGEN). cDNA was generated using Superscript III reverse transcriptase (ThermoFisher Scientific). Sanger sequencing of regions of interest was performed using standard protocols. Primer details are available upon request.

Minigene assays were performed as previously described,[26,27] with slight modifications. This assay relies on the use of a minigene vector which contains a fragment of the *SERPING1* gene, with two exonic regions separated by an intron, cloned into the mammalian expression vector pcDNA 3.1(-), downstream of the cytomegalovirus (CMV) promoter. Following transient transfection into human cells, chimeric transcripts can be analysed by reverse transcriptase PCR (RT-PCR) and sequencing. In brief, the exon of interest and approximately 150 bp of flanking intronic sequence either side, were PCR amplified from patient and control DNA using 2X SuperFi (ThermoFisher Scientific) and cloned into the pCas2.1 minigene construct (a kind gift from Dr. Alexandra Martins) using *Bam*HI/*Mlu*I (ThermoFisher Scientific) to generate pCas2.1-STAC3_e3 (https://benchling.com/s/seq-MpmgmQUFtsZtWsXCHHS9). Wild-type and variant-containing plasmids were purified using a QIAprep miniprep kit (QIAGEN) and sequences verified by Sanger sequencing. Expression constructs were then transfected into human HEK293FT cells using Lipofectamine 3000 (ThermoFisher Scientific), and RNA harvested after 24 hours using an RNeasy mini kit (QIAGEN). cDNA was generated using SuperScript III reverse transcriptase (ThermoFisher Scientific) and chimeric cDNA amplified by RT-PCR using 2X GoTaq G2 (Promega) using forward primer KO1F (5'-TGACGTCGCCGCCCATCAC) and reverse primer pCAS2R (5'-ATTGGTTGTTGAGTTGGTTGTC) and 30 cycles of amplification. RT-PCR products were analysed on a 2% agarose gel stained with ethidium bromide (0.5 µg/mL), and gel extracted and purified using a QIAquick gel extraction kit (QIAGEN) for Sanger sequencing. Splicing differences were assessed by comparing RT-PCR and sequencing results for the wild-type and variant (c.312T>G) constructs. Sequence alignments were performed in benchling (benchling.com) using the MAFFT algorithm.

GLDN cell assay

The plasmid expressing human GLDN (hGLDN) with a myc-tag epitope at the extracellular C-terminus was obtained from Dr Jerome Devaux.[28] Site-directed mutagenesis was performed by Genscript to generate a construct containing the p.Leu20Pro substitution. HEK cells were grown in tissue culture plates as per standard conditions and transfected with either the WT or mutant hGLDN constructs using Lipofectamine 3000. After 48 hours the live cells were incubated for 2 hours with a c-myc (dylight 550) monoclonal antibody (Myc.A7, ThermoFisher Scientific) to label GLDN at the cell surface. Cells were washed 3 times for 5 minutes with PBS to remove unbound antibody and then fixed with 2% paraformaldehyde for 5 minutes. Cells were washed again 3x for 5 minutes in PBS and then blocked and permeabilised with 10% FCS and 0.1% saponin in PBS for 30 minutes. Cells were then incubated with a c-myc FITC-labeled monoclonal antibody (FITCR953-25, ThermoFisher Scientific) to label total GLDN and then washed in PBS containing Hoechst to label nuclei. Imaging was performed on a Nikon inverted microscope.

RESULTS AND DISCUSSION

Diagnostic yield

Through diagnostic and/or research testing (including bespoke targeted neurogenetic disease gene panels and whole exome sequencing) we investigated the genetics of a cohort of 190 Australasian cases with a primary diagnosis of arthrogryposis, fetal akinesia or multiple pterygium syndrome. A genetic diagnosis was obtained in 81 cases (42.6% diagnostic yield, Table 1, Supplementary Table 2). Fifty variants not previously associated with disease were identified (Supplementary Table 2).

TTN was the most frequently identified causative gene (*n*=8). Of the eight *TTN* cases, two showed striking amyoplasia – a feature which has previously been described in congenital titinopathy.[14] Five patients harboured variants within the triplicate repeat region of *TTN*, which is frequently poorly sequenced on exome sequencing.[29] The most frequently observed pathogenic variant within the cohort is the common 1 bp duplication in *CHRNG* (rs774279192)[30] which was present on five alleles (allele frequency 0.0132). The allele frequency of this variant in gnomAD is 0.000343 (97 of 282,834 alleles).

Recently described genes represent a substantial proportion of diagnoses

Of the 81 cases, 26 harboured variants in genes which were added in v2 and v3 iterations of the targeted gene panel (*BICD2*, *ECEL1*, *MAGEL2*, *MYO18B*, *NALCN*, *PIEZO2*, *STAC3*, *ZC4H2*), or within genes not then or only recently associated with disease (*GLDN, MYL1, NUP88, SMPD4*), i.e. none were on v3 gene panel. Thus, within our cohort, the more recently identified genes for arthrogryposis and fetal akinesia made up a substantial proportion of the genetic diagnoses (32.1%, Table 1). To illustrate this point, the diagnostic yield has increased with each iteration of the comprehensive panel (v1 = 30.3%, v2 = 37.8% and v3 = 44.0%). The improved diagnostic yield in v3 of the panel is also in part due to improved coverage and uniformity of coverage thus facilitating calling of variants within the repetitive regions of *NEB* and *TTN* and the improved ability to detect CNVs due to greater and more even coverage. Three variants in *NEB* and four in *TTN* occurred within the repetitive regions which are typically refractory to mapping and sequencing with exome sequencing.

Genotype-phenotype expansions

BICD2: Interestingly, six cases harboured *de novo* variants in *BICD2*. This includes three novel variants not previously reported in the literature or in ClinVar (c.628C>A, p.His201Asn; c.1559T>C, p.Leu520Pro; c.2113G>A, pGlu705Lys). One patient with a *de novo* p.His210Asn substitution presented with arthrogryposis multiplex *congenita*, as did cases with the recurrent *de novo* p.Arg694Cys substitution.[31,32] A series of papers originally described heterozygous *BICD2* variants in families with an SMA-LED phenotype;[33-35] *BICD2*-opathies now account for cases with lethal arthrogryposis through to asymptomatic individuals with mild subclinical features (i.e. myopathic MRI).[32] Over a similar period, the PathWest Diagnostic Genomics service has performed sequencing using v2 of the panel (which includes *BICD2*) on >1,100 neuromuscular disease patients. *BICD2* variants were not identified by the PathWest Diagnostic Genomics service in any other neuromuscular disease groups. Thus, at least in the Australasian setting *BICD2* variants seem to cause arthrogryposis more frequently than the SMA-LED phenotype for which *BICD2* variants were first described.

CACNA1S: In a Caucasian family (Figure 1A) that presented with recurrent fetal akinesia, panel sequencing identified two missense VUS in the *CACNA1S* gene (c.665T>A, p.Met222Lys and c.2365C>T, p.Arg789Cys) in the proband (II:4). Sanger sequencing

confirmed the variants and showed that the c.665T>A variant was paternally inherited and the c.2365C>T variant was maternally inherited. The affected sibling (II:1) was compound heterozygous for these variants, while both healthy siblings carried only the maternal variant. Both variants were predicted to be disease-causing by MutationAssessor, MutationTaster, PolyPhen-2, PROVEAN, and SIFT. MuPro predicted that both variants reduce protein stability. Both substitutions alter highly conserved amino acids (p.Met222 to *D. rerio* and p.Arg789 to *C. elegans,* Figure 1B) and return high CADD scores (p.Met222Lys = 27.1, p.Arg789Cys = 28.9). The p.Met222Lys and p.Arg789Cys substitutions occur within an ion transport domain and an intracellular loop domain of CACNA1S, respectively. The c.665T>A variant is absent from gnomAD and c.2365C>T is present on only 2 of 157,372 alleles. Heterozygous dominantly acting variants in the *CACNA1S* gene cause malignant hyperthermia, hypokalemic periodic paralysis and thyrotoxic periodic paralysis (OMIM 114208). More recently, Schartner *et al.* identified dominant and recessive *CACNA1S* variants associated with congenital myopathy.[9] Ophthalmoplegia, ptosis and high-arched palate were common within this cohort. On muscle biopsy, central nuclei, cores and myofibre size variation were observed. Antenatal onset was detected in three of the seven families based on decreased fetal movements on ultrasound.[9] Affected individuals in two of these families had bi-allelic null alleles, and the third had a single *de novo* missense variant.[(9)] Hunter *et al*. described an isolated case with bi-allelic *CACNA1S* variants and a congenital myopathy with ophthalmoplegia.[36] The proband (II:4) in our family was a fetus in which polyhydramnios, scalp oedema, wrist contractures and talipes were detected on ultrasound. Fetal movements were reported to be reduced by the mother and the pregnancy was terminated at 26 weeks gestation (wg). Mild facial dysmorphic features were noted on autopsy, including low anterior hairline, mild hypertelorism, and moderate retrognathia. Muscle biopsy did not detect atrophy or myofibre disorganisation. A previously affected sibling (II:1) was delivered by emergency Caesarean section at week 32/40 due to placental abruption and died at 10 days of age. The pregnancy was complicated by unexplained polyhydramnios. In retrospect, reduced fetal movements (II:1) were noted compared subsequent pregnancies (II:2/II:3). Subjectively, this baby had ptosis (based on photographic review) and a broad nasal tip (II:1). Unfortunately, cell lines and/or muscle biopsy material was not available for either case for follow-up of the identified class 3 *CACNA1S* variants.

CHRNB1: In a non-consanguineous family of mixed European ancestry (Figure 2A) with recurrent lethal multiple pterygium syndrome, a novel homozygous deletion of *CHRNB1* exon 8 was identified by WES and gCNV at the Broad Center for Mendelian Genomics (Figure 2B). Both parents were shown to be carriers. This deletion was also present in the NSES data; however it was not called due to variable coverage across neighbouring exons. The deletion was confirmed by MLPA. *CHRNB1* variants are a rare cause of autosomal dominant congenital myasthenic syndrome (OMIM 616313) and have been identified to cause recessive CMS in one family (OMIM 616314). Affected individuals in this published recessive family harboured compound heterozygous variants: a 9bp in-frame deletion and skipping of exon 8 on the other allele.[37] Skipping of exon 8 resulted in almost complete loss of pentameric AChR expression. The in-frame deletion resulted in ~70% reduced acetylcholine receptor (AChR) expression.[37] In 2016, a Danish group published the identification of a homozygous 1 bp deletion in exon 1 of *Chrnb1* in Red dairy cattle with arthrogryposis multiplex *congenita*.[38] Three related stillborn calves showed severe generalised contractures of the joints of the spine and limbs. In patients with *CHRNB1*-related CMS there is some residual AChR expression, however in the calves, complete loss of *CHRNB1* resulted in a lethal presentation. These data support the severe phenotype in our family with homozygous exon 8 deletion.

FLNC: A proband (Figure 3) presented at birth with hip dislocation, clenched hands, adducted thumbs, small mouth and high palate, and posteriorly rotated ears. On examination, she had mild arthrogryposis, reduced shoulder movement, elbow dimples and scoliosis. She remained undiagnosed after testing on a commercial arthrogryposis gene panel (143 genes). Trio whole exome sequencing identified a missense variant in *FLNC* (c.3557C>T, p. Ala1186Val). *FLNC* variants are associated with myofibrillar myopathy and distal myopathy[39] and increasingly with cardiomyopathies. Recently, Kiselev *et al.* described a series of four cases with early-onset restrictive cardiomyopathy (RCM) and congenital myopathy.[40] Three of these cases harboured the same *de novo* variant identified in our family and two of these also presented with arthrogryposis at birth. The RCM presented between 6 months and 15 years of age with the median onset of ~2 years of age.[40] Follow-up echocardiogram at 5 years of age in our proband showed a mildly dilatated left atrium, with otherwise normal heart structure and function.

Cardiac surveillance in these cases is important and this work highlights the importance of an accurate genetic diagnosis for optimal clinical care.

GMPPB: In a case from the NICU, that was born after a history of reduced fetal movements, known biallelic *GMPPB* variants were identified (c.220C>T, p.Arg74* and c.1081G>A, p.Asp361Asn). In another family, 18 week gestation ultrasound detected hydrops, pterygia and talipes; the pregnancy was terminated at 20 wg. Post mortem reported facial dysmorphism with wide-set eyes, bilaterally low-set ears, retrognathia and a wide mouth. There was a cleft of the soft and hard palate. Multiple pterygia were noted, including the elbows, shoulders, knees and hips; there was also severe bilateral talipes. Palmar and finger creases were absent. There was thin muscle in all limbs and the psoas appeared similarly. CNS examination showed an overall small brain with a small hypoplastic cerebellum and suggestion of delayed sulcation. There was ambiguous genitalia. Babygram was normal. CGH array revealed a normal female karyotype. Bi-allelic missense variants were identified in *GMPPB* (c.95C>T, p.Pro32Leu and c.1069G>A, p.Val357Ile). Recessive variants in *GMPPB* were initially described in patients with congenital and limb-girdle muscular dystrophies.[41] Bi-allelic *GMPPB* variants have since been described in patients with diverse phenotypes including congenital myasthenic syndrome and isolated episodic rhabdomyolysis.[20,42] Our cases represent a substantial phenotypic expansion of *GMPPB* disease.

SCN4A: Two families within this cohort harboured bi-allelic variants in *SCN4A*. We previously described one of these families, that presented with recurrent lethal amyoplasia, in an autosomal recessive *SCN4A* cohort paper.[12] In the second family, bi-allelic novel missense variants were identified (c.2266C>T, p.Arg756Cys and c.4433C>T, p.Ser1478Leu) in a fetus with distal arthrogryposis. This case had contractures of all limbs and polyhydramnios. The pregnancy was terminated at 22 wg. Both substitutions alter highly conserved amino acids (conserved to *D. melanogaster*, Figure 1C) and are predicted to be deleterious by SIFT and probably-damaging by PolyPhen-2; CADD scores of 32 (p.R756C) and 27.4 (p.S1478L). The p.Ser1478 residue lies within the S4-5 loop of the fourth domain which is involved in channel inactivation. Previous work showed that substitution of p.Ser1478 to cysteine enhanced channel in-activation, i.e. partial loss of function.[43] It would be anticipated that the p.Ser1478Leu substitution would also

generate a channel with partial loss-of-function. Based on this, these variants are highly suspicious but remain Class 3 variants under ACMG guidelines; functional validation of these variants is required to substantiate causality. More recently, *SCN4A* variants were postulated to cause sudden infant death syndrome.[44]

STAC3: In a consanguineous family (Figure 4A) with a history of recurrent fetal akinesia and limb contractures detected on first-trimester ultrasound, we identified a homozygous missense variant in *STAC3* (exon 3, c.312T>G, p.Asp104Glu) in the proband (II:3). Both parents were found to be carriers, and sequencing of DNA from formalin-fixed paraffin-embedded tissue of the first affected fetus (II:1) showed this case was also homozygous for the *STAC3* variant. This variant is absent from gnomAD and affects a highly conserved amino acid. Splicing predictors in Alamut suggested the variant introduced a cryptic donor splice-site. To investigate this possibility, we generated minigene constructs containing the normal exon 3 or the variant exon 3. Studies of RNA (produced in HEK cells) showed that the variant resulted in skipping of the last 22 nucleotides of exon 3 from the mRNA (Figure 4B-C). The consequence of this variant is then (c.313_334del, p.Asp104Glu*fs**73) which is likely to lead to a loss of function. A homozygous missense variant (p.Trp284Ser) in *STAC3* was originally identified as the cause of Native American myopathy.[45] This variant has since been identified in other populations. Zaharieva *et al.* identified 18 patients from 12 families presenting with a congenital myopathy with dysmorphic features and susceptibility to malignant hyperthermia.[46] Seventeen cases were homozygous for the p.Trp284Ser variant, and another proband was compound heterozygous for this variant and an essential splice site variant (c.997-1G>T). Functional analysis has shown reduced sarcoplasmic reticulum Ca^{2+} release in response to KCl depolarisation in patient myotubes.[(46)] Affected cases from our family are likely *STAC3* nulls and thus the very early and severe presentation in our cases fit with the genotype. In support of this, *Stac3* null (*Stac3*$^{-/-}$) mice are born at near Mendelian ratios but are all found dead at birth, and show curved bodies and dropped forelimbs.[47] When dissected from the uterus, *Stac3*$^{-/-}$ fetuses did not move or respond to touch but did have a heartbeat. Histologically, muscle from *Stac3*$^{-/-}$ mice showed central nuclei, reduced myofibril number and size and deranged sarcomeres.[47] STAC3 appears to be critical to normal muscle development and function. Thus, bi-allelic loss-of-function

variants in genes critical to excitation-contraction coupling (*CACNA1S, SCN4A, STAC3, RYR1*)[5,9,11,12,48] cause lethal early-onset disease.

Identification of variants in novel human disease genes

Four cases harboured variants in disease genes that had not been described at the time of whole exome sequencing (*GLDN*,[28] *MYL1*,[16] *NUP88*[15] and *SMPD4*[49]).

The identification of a proband within this cohort with a homozygous *MYL1* missense variant, and another with compound heterozygous variants in *NUP88,* were recently described in separate publications, which also combined additional cases from other research centres with bi-allelic variants in these genes.[15,16]

GLDN: In a family from Hong Kong (Figure 5A) with a history of recurrent fetal akinesia, we identified two VUS in the gliomedin gene (*GLDN*). The first affected baby was born at 36/40 and died at 1 day of age. She had hypoplastic heart and lungs and a high-arched palate. In the second pregnancy, the fetus presented at 18/40 with decreased fetal movements and the pregnancy was terminated at 22 wg. In the third pregnancy, reduced fetal movements were reported at 20/40 and the pregnancy was terminated at 22 wg. This case had fetal hydrops, multiple joint contractures, pterygia and increased muscle bulk. All three affected cases harboured bi-allelic *GLDN* variants: a maternally inherited missense variant, c.59C>T [p.Leu20Pro], and a paternally-inherited essential splice site (ESS) change, c.363+1G>A (Figure5A). Analysis of cDNA derived from muscle from the second case indicated that the missense variant was homozygous at the transcript level, suggesting loss of expression from the allele harbouring the ESS change (Figure 5B). Using the myc-GLDN reporter assay defined in Maluenda *et al*.[28] we showed that, unlike WT human GLDN (hGLDN), gliomedin containing the p.Leu20Pro substitution fails to localise at the surface membrane of HEK cells (Figure 5C). In comparison, Maluenda *et al*. found that gliomedin mutants failed to localise at the cell surface and also did not bind its axonal partner neurofascin-186. Thus, the *GLDN* variants identified in our family are likely functional nulls.

SMPD4: A consanguineous family, from Melbourne, presented with recurrent arthrogryposis multiplex *congenita* and complex brain malformations (Figure 6A). All

cases presented with AMC, were small for gestation age and displayed hypoplasia of the corpus callosum (Figure 6B). Additional features present in two of the three cases included: congenital encephalopathy and microcephaly, cerebellar malformation and hypoplasia (Figure 6B) and hypomyelination (Figure 6C). We performed panel sequencing on the proband (II:3) with the v3 muscle and v3 neuro panels but did not identify any causative variants. We subsequently performed trio whole exome sequencing and identified a novel homozygous missense variant in the *SMPD4* gene (c.575C>T, p.Pro192Leu) in the proband. Each parent was a carrier. This variant was confirmed by bi-directional Sanger sequencing and we also showed that an affected sibling (II:1) was homozygous for this variant. The *SMPD4* variant was also homozygous in a clinical exome (performed elsewhere) on the most recently affected baby (II:4). The variant is predicted to be damaging by MutationTaster, SIFT and PolyPhen-2 and has a CADD score of 22.8. The variant is present on three alleles in gnomAD and alters a highly conserved amino acid (up to *D. rerio*, Figure 6D). *SMPD4* was recently described as a likely disease gene for a syndrome presenting as a skeletal dysplasia with cortical malformations and epilepsy.[50] In a follow-up study, 12 families with bi-allelic *SMPD4* variants and a phenotype encompassing microcephaly, hypomyelination, cerebellar atrophy, congenital arthrogryposis and fetal/postnatal demise were described.[49] *SMPD4* encodes the neutral sphingomyelinase-3; sphingomyelinases are important for the properties of cell membranes and the regulation of transmembrane and peripheral membrane proteins, they are also highly enriched in the nervous system. Magini *et al.*[49] showed via over-expression studies that SMPD4 localises to the ER and nuclear envelope. Immunoprecipitation assays revealed that SMPD4 interacts with several nuclear pore proteins; highlighting a role for the nuclear pore in the disease pathogenesis. In support of this, the role of the nuclear pore in human disease is becoming increasingly recognised.[51,52]

Conclusions

The utility of next generation sequencing in arthrogryposis and fetal akinesia is undeniable, yielding a genetic diagnosis in 42% of cases. In many instances, couples have gone on to have IVF and preimplantation genetic diagnosis or prenatal genetic diagnosis of subsequent pregnancies.

Of note is the substantial contribution of relatively recently identified disease genes and the large muscle genes (*NEB, RYR1* and *TTN*) to disease burden. Previously, most cases did not receive a genetic diagnosis. The clinical and genetic heterogeneity, along with the sporadic nature of the disease or small families, meant that genetic testing was difficult or unattainable beyond a handful of known genes or gene hotspots. The number of genes known to cause these diseases and the phenotypic expansions associated with known genes has been quite remarkable. In this report we show that homozygous null variants in *CHRNB1* or *STAC3* and known *GMPPB* variants cause lethal fetal akinesia, expanding the phenotypes associated with each of these genes.

Moving forward, it is critically important that interdisciplinary teams discuss interpretation of VUS in candidate genes and perform functional genomics to reclassify VUS as likely pathogenic or benign. Alternative splicing appears to be a particularly important mechanism underlying protein regulation in skeletal muscle.[53] Thus, splicing defects represent a substantial contribution to muscle disease burden.[29,54]

Submission of variants into well-curated gene databases (e.g. the LOVD) is also critical to the reclassification of VUS and mapping of known phenotype-genotype associations. Identification of the same rare VUS in two unrelated patients with a similar clinical presentation will facilitate reclassification as likely-pathogenic. By way of illustration, we identified in the research laboratory a then novel, *de novo* missense variant in *BICD2* in a patient with arthrogryposis multiplex *congenita*. The diagnostic laboratory within PathWest had a similar case with the same *BICD2* variant. Follow-up revealed that the variant in this diagnostic case had also arisen *de novo*.[31] In the words of Johan den Dunnen: many VUS may be "*variants of under sharing*" (International Congress of the World Muscle Society 2019, Copenhagen).

As the affordability of and availability of massively parallel sequencing has improved, variant interpretation has become the new bottleneck in accurate genetic diagnosis. Scalable, relatively robust and affordable assays (e.g. the cell-surface localisation assay for gliomedin) that can be utilised to assay VUS in multiple genes should be an ideal that the rare diseases community work towards. Saturation mutagenesis together with appropriate functional read-outs[55] have already been performed for some common

disease genes including *BRCA1* and *PTEN*.[56,57] A historical mutagenesis study of a small region of the SCN4A protein to cysteines informed our interpretation of the likely pathogenicity of a Class 3 variant in this gene,[43] and highlights the clinical utility of such experimental work.

Based on studies in model organisms,[58,59] it is likely that many more fetal akinesia and arthrogryposis genes await discovery. Exome and genome sequencing, along with RNA-seq in genetically unresolved cases, will likely identify additional novel disease genes.

ACKNOWLEDGEMENTS

We thank the patients and their families for participating in this study. This work was supported by the Australian National Health and Medical Research Council (NHMRC) Fellowships APP1122952 and APP1117510 to GR and NGL, NHMRC project grant APP1080587 to GR and NGL, the Association Francaise contre les Myopathies (18724) to GR. Sequencing and analysis were provided by the Broad Institute of MIT and Harvard Center for Mendelian Genomics (Broad CMG) and was funded by the National Human Genome Research Institute, the National Eye Institute, and the National Heart, Lung and Blood Institute grant UM1 HG008900 and in part by National Human Genome Research Institute grant R01 HG009141.

COMPETING INTERESTS

The authors do not have any competing interests to declare.

AUTHOR CONTRIBUTIONS

GR, NGL, MRD conceived the study. JSC, FF and PS performed experiments. TZ, KC, AO-L, GR, MRD, JSC, FF and PS analysed data. DM, RC, PM, BK, ME, MD, PJL, SHSC, AM, AC, FC, LH, GG and SG contributed clinical data. GR wrote the manuscript. All authors approved the final manuscript.

TABLE

***Table 1**: Causative genes identified within the 81 genetically diagnosed probands*

Gene	**Cases (n)**	***Gene***	**Cases (n)**
TTN	8	*CACNA1S*	1
TNNI2	7	*CHANB1*	1
BICD2	**6**	*FBN2*	1
NEB	5	*FLNC1*	1
CHRNG	4	*GBE1*	1
COL6A1	4	*GLDN**	1
MYH3	4	*KLHL40*	1
ECEL1	**3**	*MYL1**	1
MAGEL2	**3**	***MYO18B***	**1**
PIEZO2	**3**	*NUP88**	1
TPM2	3	*RAPSN*	1
TRPV4	3	*RYR1*	1
ZC4H2	**3**	*SMPD4**	1
ACTA1	2	***STAC3***	**1**
DYNC1H1	2	*TNNT3*	1
GMPPB	2		
NALCN	**2**		
SCN4A	2		

Genes in bold denote genes that were added into v2 or v3 of the panel. Genes tagged with an "" represent then novel human disease genes identified by WES (i.e. not on v1-3 of the panel)*

FIGURE LEGENDS

Figure 1: Bi-allelic class 3 variants in CACNA1S and SCN4A associated with fetal akinesia. (A) A pedigree co-segregating bi-allelic missense variants in *CACNA1S* with fetal akinesia and (B) conservation across species at the observed substitutions: p.Met222 and p.Arg789. (C) Evolutionarily conservation at two SCN4A residues substituted, bi-allelically, in another case of fetal akinesia. Importantly, previous work substituting p.Ser1478 to cysteine showed enhanced inactivation of the Na^+ channel. Abbreviations: d. 10 d = died at 10 days of age, TOP 26wg = termination of pregnancy at 26 weeks gestation.

Figure 2: Homozygous deletion within CHRNB1 causes lethal multiple pterygia syndrome. (A) A nonconsanguineous family with recurrent lethal multiple pterygia syndrome; IUFD: *in utero* fetal demise and TOP: termination of pregnancy . (B) Visualisation of the *CHRNB1* exon 8 deletion in the exome sequencing data from the proband (blue trace) and both parents (purple traces). The grey lines represent other samples in the same batch of CNV calling and show the average amount of noise across the region. The y-axis denotes the copy number as inferred by gCNV, and the x-axis shows the position along the gene in kilobases. The dots on the plot represent a probe for exon capture, which roughly represent exons. The copy number estimation is expected to hover around 2.0 for autosomes. For the X chromosome, the copy number estimation should hover around 2.0 for females and 1.0 for males.

Figure 3: Clinical presentation in a case with mild distal arthrogryposis due to a de novo missense variant in FLNC. Images A and B were taken at age 8 months and image C was taken at age 2 months. The images demonstrate reduced elbow extension with dimples, excessive ankle hypermobility, and subtle facial findings including plagiocephaly and micrognathia.

Figure 4: Homozygous variant in STAC3. (A) Pedigree showing segregation of a homozygous variant in *STAC3*. (B) 2% agarose gel of RT-PCR products from the *STAC3* minigene assay. WT – normal exon 3 of *STAC3*, MUT – exon 3 containing the c.312T>G variant. +P or -P indicates the cells were grown in the presence (+) or absence (-) of puromycin (to inhibit potential nonsense-mediated decay). NTC = no template control.

The red arrowhead indicates the smaller product in the samples containing the variant. Sanger sequencing of the RT-PCR product shows that this smaller product corresponds to loss of the 22 nucleotides following the variant in the cDNA (C).

Figure 5: Novel GLDN variants identified in a family with recurrent fetal akinesia. (A) Pedigree showing segregation of bi-allelic VUS in *GLDN*. (B) Sanger sequencing showed that the heterozygous c.59T>C on gDNA (in A) appeared homozygous in muscle cDNA, suggesting loss of expression from the allele containing the essential-splice site change. (C) Detection of hGLDN and mutant hGLDN fused to an extracellular myc-tag in HEK cells in culture (red) and post-fixation and permeabilization (green). Nuclei are stained with Hoechst.

Figure 6: A family with recurrent arthrogryposis and central involvement due to a homozygous missense variant in *SMPD4*. (A) Pedigree, (B) T1 midline sagittal image (Individual II:2, neonatal MRI brain scan) showing absence of the genu and rostrum, thinning and elongation of the callosal body. Microcephaly, hypoplasia of the inferior cerebellar vermis and prominent venous sinuses are also evident. (C) T2 axial image (Individual II:2) showing simplified gyration, compensatory ventriculomegaly and absent myelination. (D) Alignment showing evolutionary conservation of the p.Pro192 residue.

***Supplementary Table 2**: Genetic diagnoses made in each of the genetically-resolved 81 cases.*

Clinical Diagnosis	D-number	Setting	*Gene*	Variant/s	Inheritance mode	HPO terms
DA	D18-0172	D	*ACTA1*	c.220G>A (p.Glu74Lys)	*de novo*	Abnormality of prenatal development or birth Arthrogryposis multiplex congenita Amyoplasia
FADS	D16-1596	D	*ACTA1*	**c.440C>A (p.Ser147Tyr)**	*de novo*	Antenatal onset Fetal akinesia sequence Neonatal hypotonia Macrocephaly at birth Frontal bossing Cryptorchidism Congenital finger flexion contractures Contractures of the joints of the upper limbs Contractures of the joints of the lower limbs Aplasia/Hypoplasia of the palmar creases
AMC	D14-1209	D	*BICD2*	**c.628C>A (p.His210Asn)**	*de novo*	Arthrogryposis multiplex congenita Muscle weakness
DA	D16-0307	D	*BICD2*	**c.1559T>C (p.Leu520Pro)**	*de novo*	Arthrogryposis multiplex congenita Bulbar signs Restrictive ventilatory defect Kyphoscoliosis
LMPS	D16-0032	D	*BICD2*	c.1604C>T (p.Ala535Val)	*de novo*	Bilateral congenital talipes Congenital hip dislocation Knee flexion contracture Cryptorchidism Decreased muscle mass
AMC	D11-949[1]	D	*BICD2*	c.2080C>T (p.Arg694Cys)	*de novo*	Arthrogryposis multiplex congenita Neonatal hypotonia Respiratory distress Bilateral perisylvian polymicrogyria Hand clenching Talipes Micrognathia
AMC	D13-094[1]	R	*BICD2*	c.2080C>T (p.Arg694Cys)	*de novo*	Reduced fetal movements Arthrogryposis multiplex congenita Bilateral perisylvian polymicrogyria Cerebellar hypoplasia Hypoplasia of the corpus callosum Femur fracture Central apnea Talipes Ulnar deviation of finger Single transverse palmian crease
DA	D13-090	R	*BICD2*	**c.2113G>A (p.Glu705Lys)**	*de novo*	Hydrops fetalis Arthrogryposis multiplex congenita Pterygium

						Rocker bottom foot Hand clenching Talipes
FADS	D16-0750	D/R	*CACNA1S*	**c.665T>A (p.Met222Lys)** **c.2365C>T (p.Arg789Cys)**	AR	Antenatal onset Talipes Polyhydramnios
LMPS	D15-1251	D/R	*CHRNB1*	**c.[(820+1_821-1)_(1044+1_1045-1)del] - hmz**	AR	Multiple pterygia
DA	D16-0492	D	*CHRNG*	c.136C>T (p.Arg46*) - hmz	AR	Distal arthrogryposis Autosomal recessive inheritance
FADS	D13-1032	D	*CHRNG*	c.459dupA (p.Val154Ser*fs**24) - hmz	AR	Arthrogryposis multiplex congenita Pretibial dimple
DA	D16- 0928	R	*CHRNG*	c.459dupA (p.Val154Ser*fs**24) - hmz	AR	Distal arthrogryposis
FADS	D18-0294	D	*CHRNG*	**c.56-1G>A** c.459dupA (p.Val154Ser*fs**24)	AR	Antenatal onset Distal arthrogryposis
DA	D14-0923	D	*COL6A1*	c.850G>A (p.Gly284Arg)	*de novo*	Hip dislocation Peripheral neuropathy Arthrogryposis multiplex congenita
DA	D17-0991	D	*COL6A1*	**c.906_920dup (p.Glu303_Arg307dup)**	NI	Hip dislocation Bilateral congenital talipes Knee flexion contracture Elbow flexion contracture
DA	D19-1254	D	*COL6A1*	**c.987_995del (p.Asp331_Val333del)**	*de novo*	Elbow flexion contracture Knee flexion contracture Hyperextensibility at wrists Long fingers Long toe
DA	D19-1391	D	*COL6A1*	**c.6248G>A (p.Gly2083Asp)**	NI	Distal arthrogryposis Myopathy Abnormal facial shape Short stature Bilateral congenital talipes Limb-girdle muscle weakness (proximal)
DA	D08-745[2]	D	*DYNC1H1*	c.1792C>T (p.Arg598Cys)	NI	Distal arthrogryposis
DA	D14-1028[2]	D	*DYNC1H1*	c.2327C>T (p.Pro776Leu)	*de novo*	Distal arthrogryposis
DA	D16-0968	D	*ECEL1*	**c.1339C>T (p.Arg447Cys) - hmz**	AR	Antenatal onset Arthrogryposis multiplex congenita Unilateral ptosis Nonprogressive Muscle weakness
DA	D16-1653	D	*ECEL1*	**c.110_155del (p.Phe37Cys*fs**151)** **c.589G>A (p.Gly197Ser)**	AR	Flexion contracture (multiple) Aortic root aneurysm Progressive sensorineural hearing impairment Midface retrusion Micrognathia

DA	D18-0102	D	*ECEL1*	**c.1408-1G>T - hmz**	AR	Progressive distal muscle weakness Lower limb muscle weakness Onset (assymetric L>R) Elevated serum creatine kinase Myopathy
DA	D17-1980	D	*FBN2*	**c.3968G>C (p.Cys1323Ser)**	AD	Distal arthrogryposis
DA	D15-1576	R	*FLNC*	c.3557C>T (p.Ala1186Val)	*de novo*	Hand clenching Hip dislocation Hitchhiker thumb Distal arthrogryposis Scoliosis High palate Posteriorly rotated ears
DA	D18-0978	D	*GBE1*	**c.708G>C (p.Gln236His)** 691+2T>C	AR	Arthrogryposis multiplex congenita
FADS	D12-950	R	*GLDN*	**c.59T>C (p.Leu20Pro)** **c.363+1G>A**	AR	Fetal akinesia sequence Decreased fetal movement Arthrogryposis multiplex congenita Hydrops fetalis Pterygium Hypoplastic heart Pulmonary hypoplasia Skeletal muscle hypertrophy High palate
DA	D19-0998	D	*GMPPB*	c.220C>T (p.Arg74*) c.1081G>A (p.Asp361Asn)	AR	Arthrogryposis multiplex congenita Knee flexion contracture Hip contracture Flexion contracture of finger Wrist flexion contracture Stiff shoulders Overlapping fingers Talipes Limited elbow extension Amyoplasia (not typical) Decreased fetal movement (antenatal) Diaphragmatic paralysis Elevated serum creatine kinase Hirsutism
DA	D18-0741	D	*GMPPB*	c.95C>T (p.Pro32Leu) c.1069G>A (p.Val357Ile)	AR	Antenatal onset Hydrops fetalis Abnormal facial shape Small anterior fontanelle Sagittal craniosynostosis Hypertelorism Wide mouth Retrognathia Cleft palate

						Webbed neck Low-set ears Multiple pterygia Bilateral talipes equinovarus (severe) Abnormality of the musculature of the limbs Abnormality of brain morphology
DA	D16-1428	D	*KLHL40*	c.602G>A (p.Trp201*) - hmz	AR	Antenatal onset Arthrogryposis multiplex congenita
DA	D18-2007	D	*MAGEL2*	**c.1869dup (p.Thr624His*fs**89)**	NI	Elbow flexion contracture Flexion contracture of fingers and thumbs Hand clenching Torticollis
DA	D16-1250	D	*MAGEL2*	**c.1880G>A (p.Trp627*)**	*de novo*	Antenatal onset Arthrogryposis multiplex congenita Flexion contracture (all major joints) Hypertonia Elevated serum creatine kinase
DA	D18-1694	D	*MAGEL2*	**c.2895G>A p.(Trp965*)**	paternal (imprinted gene)	Distal arthrogryposis Obstructive sleep apnea Bulbar signs Feeding difficulties
DA	D16-1217	D	*MYH3*	**c.725C>G (p.Ser242Cys)**	*de novo*	Distal arthrogryposis
DA	D19-0178	D	*MYH3*^	**c.1539C>G (p.Asp513Glu)** **c.2036C>T (p.Thr679Ile)** **c.2113A>C (p.Ile705Leu)**	AD	Distal arthrogryposis Micrognathia Chin with H-shaped crease
DA	D14-0774	D	*MYH3*	c.2014C>T (p.Arg672Cys)	NI	Antenatal onset Abnormal facial shape
DA	D19-0489	D	*MYH3*	**c.2474T>G (p.Val825Gly)**	NI	Distal arthrogryposis Adducted thumb Bilateral talipes equinovarus Micrognathia Respiratory infections in early life
DA/CM	D14-1355[3]	R	*MYL1*	c.488T>G (p.Met163Arg) - hmz	AR	Decreased fetal movement Apnea Respiratory insufficiency due to muscle weakness Generalized hypotonia Myopathic facies Axial muscle weakness High palate
FADS	D17-0045	D	*MYO18B*	**c.193C>T (p.Arg65*)** **c.1537G>C (p.Ala513Pro)**	AR	Antenatal onset Hypoplasia of the musculature Elbow flexion contracture Knee flexion contracture Hip contracture Pterygium

						Cystic hygroma Dextrotransposition of the great arteries Ventricular septal defect Hypoplastic left heart Abnormal cerebral morphology
DA/CM	D18-0198	D	*NALCN*	**c.1745A>G (p.Tyr582Cys)**	*de novo*	Distal arthrogryposis
DA	D16-1913	D	*NALCN*	c.3542G>A (p.Arg1181Gln)	*de novo*	Antenatal onset Hand clenching

Numbers in superscript denote reference pertaining to the case where cases were published previously as case reports, as part of gene-specific cohort studies or novel disease gene discoveries. Setting describes whether the case was sequenced and analysed in a diagnostic (D) or research (R) laboratory or both (D/R). Variants in bold represent variants, that to the best of our knowledge have not been previously described as disease-causing. ~denotes variants within the triplicate repeat region of NEB and TTN. AMC = arthrogryposis multiplex congenita, CM = congenital myopathy, DA = distal arthrogryposis, EV = Escobar variant, FADS = fetal akinesia deformation sequence, hmz = homozygous, LMPS = lethal multiple pterygium syndrome. MYH3^ represents a variant allele present in the proband, affected father and affected paternal uncle. NI = no information.
